The Lawrence Livermore National Laboratory Livermore Site Ground Water Project is supported by many people. The dedication and diverse skills of all these individuals have contributed to the ongoing success of the Environmental Restoration Department activities. The editors wish to collectively thank all the contributing people and companies.

Summary

When the final FY 2008 Omnibus Appropriations Bill was passed by Congress, the Livermore project received only about 50% of the requested budget. Although funding was ultimately restored in late July, the budget reduction necessitated a dramatic reduction in both staff and cleanup activities at the site. Consequently, enhanced source area remediation (ESAR) pilot tests begun in 2007 were put on hold and existing ground water and soil vapor treatment operations were significantly curtailed during the year. Despite the shortfall, 2008 restoration activities for the Lawrence Livermore National Laboratory (LLNL) Livermore Site Ground Water Project included:

- Removing approximately 38.5 kilograms (kg) of Volatile Organic Compounds (VOCs) from ground water and 52.9 kg from soil vapor (Table Summ-1).
- Maintaining 29 ground water treatment facilities and 9 soil vapor treatment facilities as long as budget, staffing and facility conditions allowed.
- Maintaining a network of 95 ground water extraction wells, 1 ground water injection well, 27 dual extraction¹ wells, 31 soil vapor extraction wells, and 1 soil vapor injection well.
- As funding permitted, continuing significant hydraulic control and treatment of plumes along the western margin of the site, where concentrations of VOCs remained relatively stable during the year.
- Confirming that tritium activities in ground water samples from all wells remained below the 20,000 picocuries per liter Maximum Contaminant Level (MCL) and continued to decline by radioactive decay.
- Submitting the 2007 Annual Report and 2008 quarterly reports in compliance with regulatory agreements.

Ground water concentration and hydraulic data collected and analyzed during 2008 indicates there was very little change in the VOC concentrations and areal extent of the contaminant plumes. Hydraulic containment along most portions of the western and southern boundaries of the site was maintained and limited progress was made towards cleanup of interior plumes and source areas.

Since funding was restored in July 2008, an intensive effort has been underway to restore operations at Livermore Site facilities that were shut down or now require repair due to deferred maintenance resulting from lack of sufficient funding. This effort is expected to accelerate during 2009. With the ongoing reactivation of treatment facilities in the last quarter of 2008 and the first quarter of 2009, hydraulic control is expected to be fully restored along both the western and southern boundaries of the site by the end of March 2009.

Since remediation began in 1989, nearly 3.6 billion gallons of ground water and more than 337 million cubic feet of soil vapor have been treated, removing an estimated 2,709 kg of VOCs (Table Summ-2) from the subsurface.

¹Extraction of ground water using a downhole pump with concurrent application of vacuum to the well. Ground water and soil vapor are removed in separate pipe manifolds and treated.

Table Summ-1. Summary of 2008 Livermore Site VOC remediation.

Treatment area ^a	Volume of ground water treated (Mgal) ^b	Estimated VOC mass removed from ground water (Kg) ^c	Volume of soil vapor treated (Kft ³) ^b	Estimated VOC mass removed from soil vapor (Kg) ^c	Estimated VOC mass removed (Kg) ^{c, d}

1. Introduction

This report summarizes the Lawrence Livermore National Laboratory (LLNL) Livermore Site Ground Water Project (GWP) field and regulatory compliance activities, and the remedial action program, for calendar year 2008. The field activities section describes ground water monitoring and the Enhanced Source Area Remediation (ESAR) activities. The remedial action program section describes treatment facility operations, ground water discharges, remediation performance evaluation, and decision support analysis. The treatment areas, treatment facilities, and wells at the Livermore Site are shown in Figures 1 and 2 (a, b, c, d). Table 1 presents the type and number of wells at the site, Table 2 defines the treatment facility abbreviations used in this report, Table 3 summarizes treatment facility discharge sampling locations, and Table 4 summarizes extraction well performance during 2008.

When the final FY 2008 Omnibus Appropriations Bill was passed by Congress, the Livermore project received only about 50% of the requested budget. Staffing was drastically reduced to remain within the remaining budget and a number of treatment facilities were shut down to meet this new, much-reduced funding and staffing level. Other facilities became non-operational during the year and were not repaired due to insufficient resources. In late July 2008, funding was restored and the process to re-start the treatment facilities began. During the first quarter of Fiscal Year (FY) 2009, TF406 and TFA-E were restarted. At the end of calendar year 2008, the following facilities were awaiting re-activation: TFA, TFC-E, TFC-SE, TFD, TFD-HPD, TFD-S, VTFD-ETCS, VTFD-HPD, VTFD-HS, TFE-E, TFE-HS, TFE-SE, VTFE-ELM, VTFE-HS, TFG-N, TF406-NW, VTF406-HS, VTF511, TF518 North, TF518-PZ, VTF518-PZ, TF5475-1, TF5475-2, TF5473-3, and VTF5475. The following facilities remained operational during calendar year 2008: TFB, TFC, TFD-E, TFD-SE, TFD-SS, TFD-W, TFE-NW, TFE-SW, TFE-W, and TFG-1. Details of 2008 treatment facility operations are described further in Section 4.1 of this report.

2. Regulatory Compliance

In 2008, the Department of Energy (DOE)/LLNL submitted the GWP 2007 Annual Report (Karachewski et al., 2008) and GWP quarterly self-monitoring reports (Yow and Wong 2008a, b, c, and 2009) on schedule. Livermore Site community relations activities in 2008 included communications with neighbors and community organizations on a periodic basis; maintaining the Environmental Information Repositories and the Administrative Record; conducting tours of site environmental activities on request; and responding to public and news media inquiries. In addition, DOE/LLNL met with the Community Work Group and members of Tri-Valley Communities Against a Radioactive Environment and their scientific advisor as part of the activities funded by a U.S. Environmental Protection Agency (EPA) Technical Assistance Grant. Community questions were also addressed via electronic mail, posted mail or by telephone, and project documents, letters, and public notices were posted on a public website: <https://www-envirinfo.llnl.gov/>

3. Field Activities

3.1. Ground Water Monitoring

During 2008, the FY08 budget reduction necessitated a change in the way that ground water levels and ground water chemistry were monitored at the Livermore Site. Due to staffing shortages, ground water level measurements were taken once a quarter rather than once a month, as in previous years. Because of limited funding, monitor well sampling was curtailed, and strict adherence to the quarterly sampling recommendations specified by the Cost Effective Sampling (CES) algorithm was not possible. Accordingly, a modified program based on the CES algorithm was developed. This program gave a high priority to sampling at a) wells downgradient of idled treatment facilities to monitor for any movement of contaminants out of areas where hydraulic containment was no longer being provided, and b) locations where contaminant concentrations were increasing. The modified sampling program was used through the fourth quarter of 2008. Quarterly sampling was once again fully compliant with the CES Algorithm in the first quarter of 2009.

3.1.1. Ground Water Level Measurements

Ground water level measurements are normally taken from approximately 590 wells on a monthly basis. These data are complimented by continuous ground water level measurements collected from extraction wells at the treatment facilities. In 2008, monthly ground water levels were taken for the first two months of the year. Due to the budget reduction, ground water level measurements were taken once per quarter rather than once a month, starting April of 2008. A total of 2,966 ground water level measurements were taken in 2008. Because of the discontinuous operations in 2008, ground water level measurement efforts required a higher degree of coordination than normal with the treatment facility operations to collect data representative of subsurface conditions. Monthly ground water level measurements are scheduled to resume during the second quarter of 2009.

3.1.2. Ground Water Sampling

LLNL Environmental Restoration Department (ERD) and Permits and Regulatory Affairs Division (PRAD) personnel evaluated data quality objectives, analytical results, historical trends, the CES algorithm, and hydraulic data to determine the sampling frequency, chemical analyses, and methods for collecting ground water samples. The ground water samples were analyzed for Volatile Organic Compounds (VOCs), fuel hydrocarbons, polychlorinated biphenyls, metals, radionuclides, or combinations thereof depending upon the location.

During 2008, the GWP was able to collect samples from 303 wells. There were a total of 586 successful sampling events. The samplers were unable to collect samples from 28 wells due to various circumstances, e.g., well was dry, had an inoperable pump, etc. The methods and numbers of samples collected were:

- Specific-Depth Grab Sampling (SDGS) using the Voss EasyPump: 451 events (79%).
- Three-volume purge using a dedicated electric submersible pump: 68 events (12%).
- Low-volume purge: 11 events (2%).
- Other (bailer, electronic submersible pump, etc.): 43 events (7%).

Ongoing and significant cost reduction was achieved again in 2008 through the use of SDGS and low-volume purge methods. SDGS is the preferred method for collecting ground water samples, especially at well locations where the purge water might contain mixed waste consisting of both VOCs and tritium. The benefits of these methods include:

- Eliminating the need to replace dedicated pumps and related sampling equipment,
- Increasing technician efficiency and reducing sampling time,
- Increasing personnel safety through the use of low voltage equipment, and
- Eliminating collection, treatment, and disposal of more than 50,000 gallons of purge water, including water that would be considered mixed waste due to the presence of both VOCs and tritium.

3.2. Enhanced Source Area Remediation Activities

In 2007, DOE/LLNL increased its efforts to identify and evaluate innovative technologies that could help accelerate cleanup of contaminant source areas at the Livermore Site. These efforts, which collectively are called Enhanced Source Area Remediation (ESAR) activities, include detailed hydrogeologic evaluation, numerical modeling, bench-scale laboratory tests, and field treatability tests (Karachewski et al., 2008). Because of the budget reduction in 2008, DOE/LLNL reprioritized its activities to focus on operation and maintenance of existing ground water and soil vapor treatment facilities. Accordingly, ESAR-related work was largely limited to documenting activities that had occurred in 2007.

3.2.1. Source Area Cleanup Technology Evaluation

A data evaluation and numerical modeling analysis methodology called the Source Area Cleanup Technology Evaluation (SACTE) analysis was developed by ERD to evaluate potential technologies to accelerate source area cleanup (McNab, 2007). During early 2008, field data collected from ESAR treatability tests conducted at the TFE Eastern Landing Mat (TFE-ELM), Trailer T5475 (T5475), and TFD Helipad were analyzed to assess the effectiveness of the following cleanup technologies:

- Dynamic wellfield operations for removing residual contamination in the vadose zone (TFE-ELM and T5475),
- Hot air injection and ground water heating for accelerating contaminant mass removal from both the capillary fringe and the vadose zone (TFE-ELM), and
- Chemical oxidation and bioremediation for in-situ destruction of contaminant mass in the saturated zone (TFD Helipad).

Due to the budget reduction, these analyses were halted in February 2008. As staff resources become available, ERD plans to resume this evaluation. ESAR activities in the three source areas are discussed below.

3.2.2. Trailer 5475 Source Area

In 2007, two operational modes for testing dynamic wellfield operations (DWFOs) at T5475 were formulated. During a two-week period in September 2007, modes I and II were evaluated during facility start up. Mode I consisted of injecting treated vapor effluent into wells east of T5475 while simultaneously extracting soil vapor from wells on the western side of the trailer

(Fig. 2d). During mode II, the injection and extraction well locations were reversed. Concentrations consistently above those being removed using the original remedial wellfield and associated pipelines were measured (6 to 8 parts per million on a volume basis (ppmv) on average, versus, the previous average of 1 to 2 ppmv), suggesting improved removal of mass from the subsurface due to the additional soil vapor extraction wells and dynamic wellfield operations. A letter report summarizing these findings was submitted to DOE in July 2008 (Sicke et al., 2008a).

3.2.3. TFE Eastern Landing Mat Source Area

In late 2007, DWFOs were tested at TFE-ELM (Fig. 1) as a means of evaluating, and if necessary removing, residual contamination present in the eastern wellfield vadose zone. Over a two-month period, four modes of DWFO were tested. No total VOC concentrations above 2 ppb (by volume) were measured during the test period, confirming earlier findings indicating that the vadose zone in the vicinity of the VTFE-ELM eastern wellfield contains only very low concentrations of VOCs, and that present-day concentrations are unlikely to further impact ground water. These findings were summarized in a letter report to DOE in June 2008 (Sicke et al., 2008b).

3.2.4. TFD Helipad Source Area

During 2007, preliminary modeling was conducted to evaluate the TFD Helipad tracer test data (Karachewski et al., 2008) and to design the amount and rate of nutrient injection and bioaugmentation required for conducting a successful treatability test. The findings of this modeling are summarized in a letter report to DOE submitted in January 2008 (McNab, 2008).

4. Summary of Remedial Action Program

This section summarizes the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) remedial action program at the Livermore Site. In 2008, DOE/LLNL maintained 29 ground water treatment facilities, as funds allowed, in the TFA, TFB, TFC, TFD, TFE, TFG, and TFH areas (Fig. 1 and Table 2). The ground water extraction and dual extraction wells produced approximately 177 million gallons of ground water and the treatment facilities removed an estimated 38.5 kilograms (kg) of VOCs (Table Summ-1, Fig. 3, and Table 4). In 2007, the ground water treatment facilities removed approximately 71 kg of VOCs. The significantly lower mass removed in 2008 reflects the smaller number of facilities and extraction wells that operated for shorter periods of time due to the budget reduction. Since remediation began in 1989, more than 3.6 billion gallons of ground water have been treated, resulting in removal of an estimated 1,356 kg of VOCs (Table Summ-2 and Fig. 3).

In 2008, DOE/LLNL also operated 9 soil vapor treatment facilities in the TFD, TFE, and TFH areas (Fig. 1 and Table 2). The soil vapor extraction and dual extraction wells produced more than 20 million cubic feet of soil vapor, and the treatment facilities removed approximately 52.9 kg of VOCs (Table Summ-1, Fig. 3, and Table 4). In 2007 the soil vapor treatment facilities removed approximately 248 kg of VOCs. The significantly lower mass removal in 2008 is primarily due to a smaller number of facilities operating for shorter periods of time due to the budget reduction. Since initial operation, more than 337 million cubic feet of soil vapor

has been extracted and treated, removing an estimated 1,353 kg of VOCs (Table Summ-2 and Fig. 3).

Treatment facility performance is evaluated using multiple data sets. Figures 4 through 9 show the estimated hydraulic capture areas in Hydrostratigraphic Units (HSUs) 1B, 2, 3A, 3B, 4, and 5, respectively, based on ground water elevation data collected during the third quarter of 2008. Figures 10 through 15 are isoconcentration maps showing total VOCs above Maximum Contaminant Levels (MCLs) in the same six HSUs during the third quarter of 2008. The estimated hydraulic capture areas for third quarter 2008 have been superimposed on these figures to highlight where hydraulic containment of contaminant plumes was achieved during this time period. Contaminant concentration trends (Section 4.3) are also used to evaluate hydraulic capture and of treatment facility performance.

4.1. Summary of Treatment Facility Operations

During 2008, nineteen Livermore Site treatment facilities were shut down due to the FY 2008 budget reduction. Four treatment facilities were manually shut down to accommodate the budget reduction, and fifteen additional facilities became non-operational during the year due to failure or maintenance needs. Two other facilities were also shutdown during 2008. One facility was shutdown due to regulatory concerns and the other facility was shutdown because elevated tritium levels were detected in the extraction well.

When funding was restored in July 2008, ERD developed a process to restart facilities in a phased and deliberate fashion based on risk to human health and the environment, and importance to the cleanup effort. In accordance with the remedial objectives and selected remedies defined in the Livermore Site Record of Decision (DOE, 1992) and subsequent CERCLA documentation, western and southern site boundary control and offsite contaminant plume clean up were given the highest priority. Treatment facilities that hydraulically control higher-concentration ground water plumes that had the potential to move beyond the reach of existing cleanup infrastructure were also considered high priority. The ERD process, known as the Remediation Evaluation (REVAL) process, is being used to carefully and systematically restart extraction wells and treatment facilities to ensure that each system operates in a safe and optimal manner to remove and treat contaminated soil vapor and ground water, and ultimately accomplish cleanup of the subsurface. ERD began using this process during 2008 to evaluate and restart facilities as expeditiously as possible, while maximizing the use of limited resources by prioritizing work scope and schedules.

In addition to the REVAL process, review and preliminary design work is underway to restart and improve the reliability of nine Livermore Site soil vapor treatment systems. Four vapor treatment facilities ceased operation due to blower motor failure, and the fifth was shut down as a precautionary measure. The cause of the blower failures is under investigation. One vapor treatment facility was shut down to avoid production of mixed waste. Another vapor treatment facility was shut down due to failure of the flow measurement equipment. One vapor treatment facility was shut down because of high operating costs. Another facility was shut down for an *in situ* bioremediation test. These facilities will be restarted once these issues have been resolved.

4.1.1. Treatment Facility A Area

Two treatment facilities, TFA and TFA East (Fig. 1), operated in compliance with all permit requirements during 2008. A third facility, TFA West, was shut down in early January due to regulatory concerns about using the Livermore Water Reclamation Plan (LWRP) for VOC treatment. A rebound test is being conducted there to determine if tetrachloroethylene (PCE) concentrations return to pre-test levels. Although self-monitoring reports continue to be submitted for this facility, there are no plans to restart it in its present configuration according to regulatory direction (Yow and Wong, 2008a, b, c, and 2009). A treatability summary report presenting cleanup alternatives will be submitted by the end of September 2009.

At TFA, the western pipeline was offline in early January due to rainwater intrusion into the mechanical vaults. Water was removed from the affected vaults and the wells were restarted. The facility was shut down intermittently in January to install electronic equipment and to conduct facility interlock checks. The south wellfield shut down for three days in late February due to heavy rain events flooding extraction well vaults. The facility was shut down from late May to mid June while the facility control system hardware underwent a complete replacement and upgrade, and during part of July while the facility control system software was updated. In early August, the facility was shut down due to multiple electronic control issues and has remained off since. An expedited REVAL process was initiated for TFA in early November to ensure rapid restart of the facility. Ground water extraction and treatment are scheduled to resume at TFA in January 2009.

TFA East shut down in early September due to electronics issues with the solar power charge controller and associated software. After completing the REVAL process, including replacement of the electrical power storage batteries and refurbishing the downhole pump equipment, the facility was restarted in early December. TFA East was temporarily shut down in mid-December for freeze protection during the year-end holidays, and was restarted on December 29, 2008.

4.1.2. Treatment Facility B Area

TFB (Fig. 1) operated in compliance with all permit requirements in 2008 except for the following discharge. Ground water was inadvertently extracted from well W-655 on February 1 and pumped to TFB while the air stripper was offline causing approximately 250 gallons of untreated ground water to discharge to the ground. The January 2008 total VOC concentration from well W-655 was 6.36 $\mu\text{g/L}$. About 125 gallons of the total volume is estimated to have infiltrated into the soil. Water did not reach the drainage ditch near TFB, and the quantity discharged was insufficient to reach ground water. The cause of the spill was a defective digital output module. The extraction well pumps were manually secured while the digital output module was replaced and corrections were made to the control system. TFB was shut down from early January to late March for electronic upgrades, and for one week in late July for flow totalizer repair.

4.1.3. Treatment Facility C Area

Three treatment facilities, TFC, TFC East, and TFC Southeast (Fig. 1), operated in compliance with all permit requirements during 2008. TFC was shut down intermittently in January due to scaling in the discharge pump, and for three days in November due to computer control issues. Ion-exchange columns were added in late November for rainy season hexavalent chromium treatment.

TFC East was shut down in late February and remained off the rest of the year due to operational cost and lack of available staff due to the budget reduction. This facility is currently undergoing the REVAL process in preparation for restart, which is scheduled for the second quarter of 2009.

TFC Southeast was shut down in early May due to control issues with the discharge pump and remained off the rest of the year due to the budget reduction. The REVAL process is underway at this facility and is expected to resume operating during first quarter of 2009.

4.1.4. Treatment Facility D Area

Five of ten treatment facilities, TFD, TFD East, TFD Southeast, TFD Southshore, and TFD West (Fig. 1), operated in compliance with all permit requirements during 2008. TFD South operated in compliance during 2008, except for the event described below. Four facilities, TFD Helipad, VTFD Helipad, VTFD East Traffic Circle South, and VTFD Hotspot, did not operate in 2008. TFD Helipad and VTFD Helipad were shut down for an ESAR bioremediation pilot test scheduled for the spring of 2008; however the test was put on hold due to the 2008 budget reduction. The Helipad facilities are scheduled to be restarted by the end of 2009. VTFD Hotspot and VTFD East Traffic Circle South did not operate due to liquid ring blower failures, and identification and resolution of the cause of failure was put on hold due to the 2008 budget reduction. These facilities are scheduled to be restarted by the end of September 2009.

TFD South was shut down in mid-May due to an extraction well transducer failure and remained off the rest of the year except for monthly compliance sampling. On May 14, a technician started the facility briefly for compliance sampling. A break in the piping from the extraction well was noticed and approximately 50 gallons of ground water was discharged from extraction well W-1503. The facility was shut down and the leak was repaired. Approximately 40 gallons was discharged onto asphalt, 5 gallons to the storm drain, and 5 gallons to the ground. The facility is still shut down for general overhaul and transducer replacement in wells W-1503 and W-1510. This facility is scheduled to undergo a REVAL-based reactivation by the end of second quarter of 2009.

The following facilities ran either continuously or intermittently throughout 2008:

- TFD was shut down in late July and remained off the rest of the year for required maintenance, including air stripper de-scaling, facility discharge pump repair, air blower exchange and Belsperse 161 sequestering agent optimization. This facility is scheduled to undergo a REVAL-based reactivation by the end of the second quarter of 2009.
- TFD East was shut down for two days in early January while the facility interface screen was replaced. The facility continued to operate throughout the year.
- TFD Southeast was shut down for four days in mid-February due to electronics problems. Well W-1403 was shut down in early July due to suspect flow meter readings and remained off the rest of the year. The facility continued operating throughout the year.
- TFD Southshore operated continuously throughout 2008.
- TFD West was shut down in late August due to a potential interlock failure in a secondary pipe leak detection system. Repairs were made and the facility was restarted in mid-September.

4.1.5. Treatment Facility E Area

Eight treatment facilities, TFE East, TFE Hotspot, TFE Northwest, TFE Southeast, TFE Southwest, TFE West, VTFE Eastern Landing Mat, and VTFE Hotspot (Fig. 1), operated in compliance with all permit requirements during 2008. TFE East was shut down for a week in mid-January due to well modification activities in the East Landing Mat (ELM) area that caused activation of the watchdog timer interlock. This facility was not operated from late-January to mid-February to modify electrical equipment at wells W-1903, W-2305, and W-1909 for the ELM ground water heating and hot air injection ESAR project. In early April, this facility was shut down due to a failed facility discharge pump. The discharge pump was serviced and the facility was restarted four days later. In early June, this facility was shut down due to control system failure and remained off the rest of the year. This facility is currently undergoing the REVAL-based reactivation process, which is scheduled to be complete by the end of September 2009.

The following facilities ran either continuously or intermittently throughout 2008:

- TFE Hotspot was shut down in early June due to erratic extraction well operations (unexplained cyclic pumping) and remained off the rest of the year. This facility is currently undergoing the REVAL process and is projected to restart in the first quarter of 2009.
- TFE Northwest operated continuously throughout 2008.
- TFE Southeast was shut down in early April due to pump and control system failures and remained off the rest of the year. This facility is projected to restart by the end of the June 2009.
- TFE Southwest was shut down for three days in mid-February due to high sump water level. This facility operated continuously for the rest of 2008.
- TFE West was shut down for three days in mid-February due to high backpressure created by water-logged granular activated carbon (GAC). The issue was corrected and the facility restarted the same day. This facility operated continuously for the rest of 2008.
- VTFE Eastern Landing Mat and VTFE Hotspot were shut down in early February due to liquid-ring blower motor failures. These facilities remained shut down for the rest of the year due to funding constraints and are projected to restart by the end of September 2009.

4.1.6. Treatment Facility G Area

Two treatment facilities, TFG-1 and TFG North (Fig. 1), operated in compliance with all permit requirements during 2008. The following facilities ran either continuously or intermittently throughout 2008:

- TFG-1 operated continuously throughout 2008. GAC was changed in December 2008.
- TFG North was shut down in late-June due to discharge pump control failure and remained off the rest of the year. This facility is scheduled for a REVAL-based restart by the end of third quarter of 2009.

4.1.7. Treatment Facility H Area

Treatment facilities in the TFH area in the southeast corner of the Livermore Site include those near buildings 406 and 518, and near trailer 5475 (Fig. 1). Facility operations in the TFH area are discussed below.

4.1.7.1. Treatment Facilities Near Building 406

Three treatment facilities, TF406, TF406 Northwest, and VTF406 Hotspot (Fig. 1), operated in compliance with all permit requirements during 2008. TF406 was shut down in mid-March due to problems with the pump in extraction well W-1310. A REVAL-based reactivation was conducted, the pump was replaced, and ground water extraction resumed in late-October. As part of the reactivation, a step-drawdown test was conducted on W-1310 to determine its sustainable yield and to establish a baseline for determining the need for well redevelopment in the future. Normal, full-time operation of this facility resumed in December.

TF406 Northwest was shut down in early February due to low influent flow rate, possibly due to bio-fouling of the pump, and remained off the rest of 2008. This facility is currently scheduled for repair and re-activation by the end of June 2009.

VTF406 Hotspot was shut down in late-June due to instrumentation issues, and remained off the rest of 2008. This facility is currently undergoing a REVAL-based re-activation and is projected to restart by March 2009.

4.1.7.2. Treatment Facilities Near Building 518

Four treatment facilities, TF518 North, TF518 Perched Zone (PZ), VTF518-PZ, and VTF511 (Fig. 1), operated in compliance with all permit requirements during 2008. TF518 North was shut down in late-February due to elevated activities of tritium in ground water from extraction well W-1410, and remained off the rest of the year. ERD is currently evaluating the situation and will prepare a schedule for a focused feasibility study by September 2009.

TF518-PZ and VTF518-PZ were shut down in late-February due to operational costs and lack of staff, and remained off the rest of the year. These facilities are currently scheduled to be restarted in FY10.

VTF511 was shut down for one week in early February due to a broken discharge pipe and for two weeks in May due to elevated temperatures at the liquid-ring blower during a heat wave. In late July, this facility was shut down due to electronic issues, and remained off for the rest of the year. This facility is currently scheduled for reactivation by the end of June 2009.

4.1.7.3. Treatment Facilities Near Trailer 5475

TF5475-2 was shut down in 2007, awaiting resolution of disposal issues due to a reported detection of low alpha contamination in the GAC. However, the LLNL Radioactive and Hazardous Waste Division discovered that the reported alpha contamination was an error, and that no mixed waste was being generated at this location. Accordingly, the GAC from TF5475-2 was classified as RCRA waste (F-listed) and not mixed waste, and the facility was restarted in mid-January after addressing mechanical and electrical issues. In late-February, this facility was shut down due to operational cost and available staffing, and remained off the rest of the year. During the approximate 1-1/2 months it was operating, this facility was in compliance with

permit requirements. This facility is currently scheduled to restart by the end of second quarter of 2009.

Treatment facilities TF5475-1, TF5475-3, and VTF5475 were shut down in 2007 due to mixed waste disposal issues, and remained shut down throughout 2008 due to computer and control system issues, budget constraints and the mixed-waste disposition issues. A schedule for focused feasibility studies to address the mixed-waste issues will be prepared by September 2009.

4.2. Ground Water Discharges

In 2008, LLNL discharged nearly 178 million gallons (Mgal) of treated ground water to the ground surface. Specifically, nearly 105 Mgal were discharged to Arroyo Las Positas, nearly 43 Mgal to the West Perimeter Drainage Channel, and approximately 30 Mgal to Arroyo Seco. In addition, more than 0.6 Mgal of filtered ground water from well W-404 were discharged to the Livermore Water Reclamation Plant.

4.3. Remediation Performance Evaluation

In 2008, with a few notable exceptions, VOC concentrations remained relatively unchanged in most Livermore Site ground water plumes. This lack of change is attributed primarily to the fact that active remediation was curtailed in many places due to the FY08 budget reduction discussed previously in this report. The 91.4 kg of VOCs removed by the ground water, soil vapor, and dual extraction wells during the year (Tables Summ-1 and Table 4) is a 71% decrease compared to the total amount of contaminant mass removed in 2007 (319 kg). This temporary disruption in mass removal rates and concentration reduction is clearly not consistent with the longer-term trends described in the 2007 Third Five-Year Review for the LLNL Livermore Site (Berg et al., 2007) that show steady mass removal and cleanup in both offsite and onsite areas. Since funding was restored in July 2008, an intensive effort has been underway to restore operations at Livermore Site facilities that were shut down or now require repair due to deferred maintenance that could not be addressed during the budget reduction. This effort is expected to accelerate during 2009.

Ground water elevation contour maps for each HSU showing estimated capture areas for the third quarter of 2008 are presented on Figures 4 through 9. Notable VOC concentrations trends and results from the third quarter 2007 through the third quarter 2008 are discussed below and are presented on isoconcentration contour maps showing VOCs above Maximum Contaminant Levels (MCLs) by HSU (Figs. 10 through 15). Treatment facilities are shown on Figures 2a through 2d. Where available and relevant, concentration data more recent than third quarter 2008 are discussed in the text below.

4.3.1. Hydrostratigraphic Unit 1B

VOC concentrations in HSU 1B remained largely unchanged in all offsite areas of the Livermore Site during 2008. West of LLNL, at the one remaining offsite well with concentrations above MCLs (W-1425) (Fig. 10), PCE concentrations declined slightly from 11 ppb in August 2007 to 9 ppb in October 2008. However, east of Vasco Road in the TFA treatment area, PCE concentrations increased at wells W-254 (from 55 ppb in April 2008 to 73 ppb in November 2008) and W-604 (from 5 ppb in August 2007 to 12 ppb in

September 2008). These increases may be due to the cessation of ground water extraction at well W-254 during the months of September, October, and November 2008 (Fig. 10) and at TFA during May, June, and mid-August through December 2008 due to the budget reduction. Concentrations are expected to start declining again in these areas since pumping resumed at well W-254 (TFA East) in December and is scheduled to resume at well W-415 (TFA) in early 2009.

In the central TFB treatment area (Fig. 1), east of the western site boundary, TCE concentrations rose significantly at onsite monitor well W-218 (12 ppb, February 2007 to 89 ppb, October 2008) (Fig. 10). This increase coincides with a decrease in pumping at adjacent HSU 1B extraction well W-704 that occurred as part of an effort to optimize mass removal in underlying HSU 2 in the TFB area. The flow rate in well W-704 was increased from 6 to 18 gpm to ensure that concentrations decline at well W-218 during the next year. Further to the west, concentrations fell at downgradient monitor well W-269 (6.6 ppb, January 2008 to 2.6 ppb, October 2008).

Elsewhere in the TFB and TFC areas, concentrations did not change significantly during 2008, and no evidence of westward migration of the contaminant plumes was observed.

As shown on Figures 4 and 10, the HSU 1B contaminant plumes along the western LLNL margin were hydraulically contained at TFB, most of TFC, and part of TFA during third quarter of 2008. Hydraulic containment along the western margin is scheduled to be fully restored at TFC-SE and TFA by the end of March 2009 once the two facilities have been reactivated through the REVAL process.

4.3.2. Hydrostratigraphic Unit 2

VOC concentrations in HSU 2 declined or remained stable in most areas along the western LLNL margin during 2008 (Fig. 11), with a few notable exceptions. Concentrations declined in the western TFA area, despite the hiatus in pumping during May, June, and mid-August through December 2008. PCE concentrations decreased at several onsite wells along Vasco Road, including W-714 (from 16 ppb in August 2007 to 8 ppb in May 2008), W-605 (from 31 ppb in April 2007 to 22 ppb in May 2008), W-118 (from 27 ppb in March 2007 to 23 ppb in January 2008), and W-614 (from 11 ppb in April 2007 to 8 ppb in April 2008).

At well W-404, west of Vasco road, where a year-long treatability test occurred during 2007 (Karachewski et al., 2008), PCE concentrations rebounded slightly from a low of 7 ppb in January 2008 to 11 ppb in October 2008. Elsewhere, PCE concentrations remained stable or declined slightly, and the 10 ppb total VOC contour almost disappearing completely from the offsite area (Fig. 11). At well W-654, PCE concentrations declined from 12 ppb in September 2007 to 7 ppb in October 2008.

In the TFB area, along the western boundary of the site, TCE continued to slowly increase at monitor well W-422, despite continuous pumping at upgradient extraction well W-655 throughout the year (from 10 ppb in October 2007 to 13 ppb in October 2008). An additional HSU 2 extraction well has been proposed for this location to more effectively contain and treat VOCs there.

In the eastern portion of the site, concentrations also remained relatively unchanged, except in the TFD East and TFD Southeast areas, where TCE decline at wells SIP-ETC-201 (from 160 ppb in April 2007 to 60 ppb in December 2007), W-1303 (from 220 ppb in October 2007 to

150 ppb in October 2008), W-1223 (from 180 ppb in October 2007 to 100 ppb in October 2008), and W-1306 (from 140 ppb in May 2007 to 100 ppb in October 2008). The decrease in TCE concentrations in this area is likely due to pumping in HSU 2 extraction wells at these two facilities throughout the year. At HSU 2 extraction well W-1404, however, concentrations continued to fluctuate, increasing from 110 ppb in October 2007 to 360 ppb in October 2008. Well W-1404 only operated sporadically during the year due to the very low sustainable yield available at this location. Elsewhere in the TFE, TFH, and TFG areas, VOC concentrations in HSU 2 did not change appreciably during 2008.

Figure 5 shows the estimated hydraulic capture areas in HSU 2 during the third quarter of 2008. Most of the contaminant plumes in the TFA and TFB areas were hydraulically contained (Fig. 11). Two exceptions include the offsite plume at well W-404 and the area immediately west of monitor well W-422 in the TFB area. By the end of March 2009, when TFA is scheduled to begin operating again, hydraulic containment along the western plume margins should be fully restored. By then, the offsite W-404 PCE plume should be within the stagnation zone of TFA west pipeline extraction well W-109.

4.3.3. Hydrostratigraphic Unit 3A

During 2008, very little change was observed in the size and location of the contaminant plumes in HSU 3A (Fig. 12). At well W-276, in the westernmost TFE area, TCE continued to decline (from 94 ppb in August 2007 to 67 ppb in October 2008). This decline is likely a response to pumping at TF406 Northwest extraction well W-1801, which operated during the fourth quarter of 2007 and January 2008. Pumping operations are expected to be restored there by mid-2009. At TFE Hotspot, TCE in well W-1201 declined from 310 ppb in February 2007 to 120 ppb in August 2008. The decline is due to ground water extraction at well W-2012. Operations at TFE Hotspot were halted in June of 2008 due to the budget reduction, and are expected to be restored by March 2009. Elsewhere in the eastern part of the site, no significant HSU 3A concentration trends were observed during 2008.

To the west in the TFA area, carbon tetrachloride along the western site boundary remained unchanged (3 ppb at well W-712 throughout the year), and PCE remained slightly above its MCL at well W-310 in TFB (6 ppb, October 2008). A pumping test is planned to determine whether the PCE in well W-310 is due to a faulty completion in either well W-310 or an adjacent well.

Figure 6 shows the estimated hydraulic capture areas in HSU 3A during the third quarter of 2008. Hydraulic containment at the TFD South, TFE Hotspot, and TF406 Northwest areas is expected to be restored by mid-2009 once these facilities have been reactivated through the REVAL process.

4.3.4. Hydrostratigraphic Unit 3B

VOC concentrations remained predominantly stable in HSU 3B during 2008, with very few locations exhibiting declines. A decrease was noted in the southern TFD and Northern TFE areas, where TCE fell in wells W-1422 (Fig. 13) (from 100 ppb in August 2007 to 18 ppb in August 2008), W-1511 (from 200 ppb in August 2007 to 140 ppb in November 2008), and W-364 (from 72 ppb in August 2007 to 59 ppb in November 2008). These reductions are in response to pumping at TFD South, TFD Southshore, and TFE West during 2008. At TFE Southwest extraction well W-1522, which operated throughout the year, TCE increased from

141 ppb in July 2007 to 232 ppb in October 2008. This increase may be related to rising water levels in the area (8 ft during the year at nearby monitor well W-356). The rise in water levels appears to be in response to a cessation in pumping at many HSU 3B extraction wells during 2008.

As shown in Figure 7, large portions of TFD, TFE, and TFH remained under hydraulic control during third quarter 2008. The area under hydraulic containment is expected to expand considerably once pumping operations are fully restored at ground water extraction facilities in these three areas.

4.3.5 Hydrostratigraphic Unit 4

Although essentially unchanged from 2007, there were several notable concentration trends observed in HSU 4 during 2008. For the first time since pump and treat remediation of HSU 4 at TF406 ceased in 2000, TCE rose above its MCL at one location (8 ppb at well W-1309, October 2008) (Fig. 14). ERD will continue to monitor VOC concentrations in well W-1309 and may resume ground water extraction at this location in 2009. The increase appears to coincide with rising HSU 4 water levels in the area (a rise of about 7 ft was observed in area wells during the year). Ground water levels appear to be recovering from overdraft conditions caused by ground water extraction at the Livermore Site.

In the northeastern TFD area, carbon tetrachloride has slowly risen above its MCL in well W-372 (Fig. 14) over the last several years (2.6 ppb, January 2007). The source of this carbon tetrachloride is not known, but may be related to carbon tetrachloride detected in the borehole of well W-594, located about 1,100 ft upgradient to the northeast (Fig. 2c). Concentrations at well W-372 will be closely monitored to determine whether remedial action is required at this location.

In the TFD South area, which was shut down in May 2008, TCE rose sharply at extraction well W-1503 (from 55 ppb, in July 2007 to 440 ppb in November 2008), indicating a rebound has occurred in the area (Fig. 14). TFD South is currently scheduled to be reactivated by June 2009.

In the TFD East area, TCE at well W-1253 fell from 3,200 ppb in September 2007 to 2,300 ppb in February 2008. In the TFE Southwest area, TCE in monitor well W-354 increased from 27 ppb in May 2007 to 100 ppb in October 2008. Adjacent TFE Southwest HSU 4 extraction well W-1520 is currently not operating due to an increase in tritium activity that was observed there during 2008 (from 2,720 pCi/L in October 2007 to 3,860 pCi/L in October 2008). The source of the increasing tritium activity is currently under investigation.

Figure 8 shows the extent of the estimated hydraulic capture areas in HSU 4 during the third quarter of 2008. The area under hydraulic capture in HSU 4 expected to expand significantly once pumping resumes at TFD South in 2009.

4.3.6 Hydrostratigraphic Unit 5

Although the general configuration and location of contaminant plumes in HSU 5 during 2008 remained essentially unchanged from 2007, some differences were observed. In the TFH area, an increase in TCE was observed west of Building 419 at well W-1413, where concentrations rose from 5 ppb in July 2007 to 61 ppb in April 2008. The increase is likely related to a cessation in pumping at TFE Southeast extraction well W-359 that occurred in April 2008, or may be related to a local rise in water levels that has been observed during the last

year (10 ft since February 2008 in well W-1413). This rise in water levels may be affecting source areas previously isolated within the vadose zone. Further to the west in the TFH area, a slight decrease was observed at the leading edge of the TCE plume in well W-1519, where TCE declined from 11 ppb in May 2007 to 8 ppb in August 2008. To the south, TCE in ground water beneath the property managed by Sandia National Laboratories rose slightly in several wells, then declined once TF406 operations resumed in October (8 ppb in October 2007 to 1 ppb in November 2008 in W-750; 7 ppb in February 2008 to 1 ppb in November 2008 in W-1113).

To the west of TFE East, TCE declined in well W-1210 from 61 ppb in October 2007 to 25 ppb in October 2008. Elsewhere in the area, TCE remained essentially unchanged during 2008. Ground water extraction in HSUs 2 and 5 is scheduled to resume at TFE East during the third quarter of 2009.

Figure 9 shows that only the area around TFD was hydraulically controlled at the Livermore Site during the third quarter of 2008. Most of the eastern TFD, TFE, and TFH areas are expected to be back under hydraulic containment once operations resume at TFE East and TFE Southeast. Operations resumed to the south at TF406 in October 2008.

During 2008, tritium activities in ground water from all wells at the Livermore Site, including those in the Trailer 5475, Building 292, and Building 419 areas (Fig. 1), remained below the 20,000 pCi/L MCL and continued to decline by radioactive decay. In the former Building 412 area (Fig. 1), tritium was measured at 14,200 pCi/L in HSU 3A well W-2205 (August 2007) (Fig. 12). The source of tritium at this location is currently under investigation.

4.4. Decision Support Analysis

Over the last several years, ERD has used a variety of decision support tools and performed various analyses to evaluate the performance of the remedial systems and to improve the quality, efficiency, and consistency of routine tasks. These decision support activities are grouped into four categories:

- Environmental Information Management System
- Automated Data Review and Mapping Tools
- Predictive Analysis Tools
- Project Management Tools

In 2008, we continued to maintain our environmental database, and associated data entry and data review tools. These tools were used on a daily basis for work tasks ranging from data entry to report preparation. For example, the treatment facility self-monitoring reporting tool allows facility operators to enter data using a web-based interface, and to automatically generate the resulting reports (Yow and Wong, 2008a, b, c, and 2009).

The next level of decision-support tools consist of sophisticated graphical, statistical, and numerical data analysis tools used for remedial performance evaluations. This suite of tools includes the CES algorithm that enables ERD personnel to quickly review concentration trends in wells and make sampling recommendations on a quarterly basis. Another frequently used tool is the Optimized Environmental Restoration Analysis (OPERA) tool. This web-tool enables ERD personnel to quickly view plume maps for each contaminant and compare current conditions with historical distributions. Approximately 7,900 plume maps and 1,800 ground water elevation maps that span the entire 21 year project history are updated each quarter within

in a matter of hours. The map library was updated once per quarter in 2008 with the most recent sampling information available, and the resulting electronic map library is accessed using the OPERA web tool.

The ERD environmental database and the data analysis tools significantly reduce the effort required to develop analytical or numerical models for predictive analyses. In 2008, predictive analysis activities were limited to Source Area Cleanup Technology Evaluation (SACTE) modeling, and Enhanced Source Area Remediation (ESAR) modeling associated with TFE Eastern Landing Mat, TFH Trailer 5475, and TFD Helipad Area activities. These analyses were discontinued in March due to staffing reductions caused by the budget reduction. Regional-scale flow and transport models were also used to evaluate the effectiveness of operating extraction well fields to prevent off-site migration of contaminant plumes. The results of these analyses allowed ERD personnel to prioritize the maintenance and operation of critical facilities to ensure hydraulic containment.

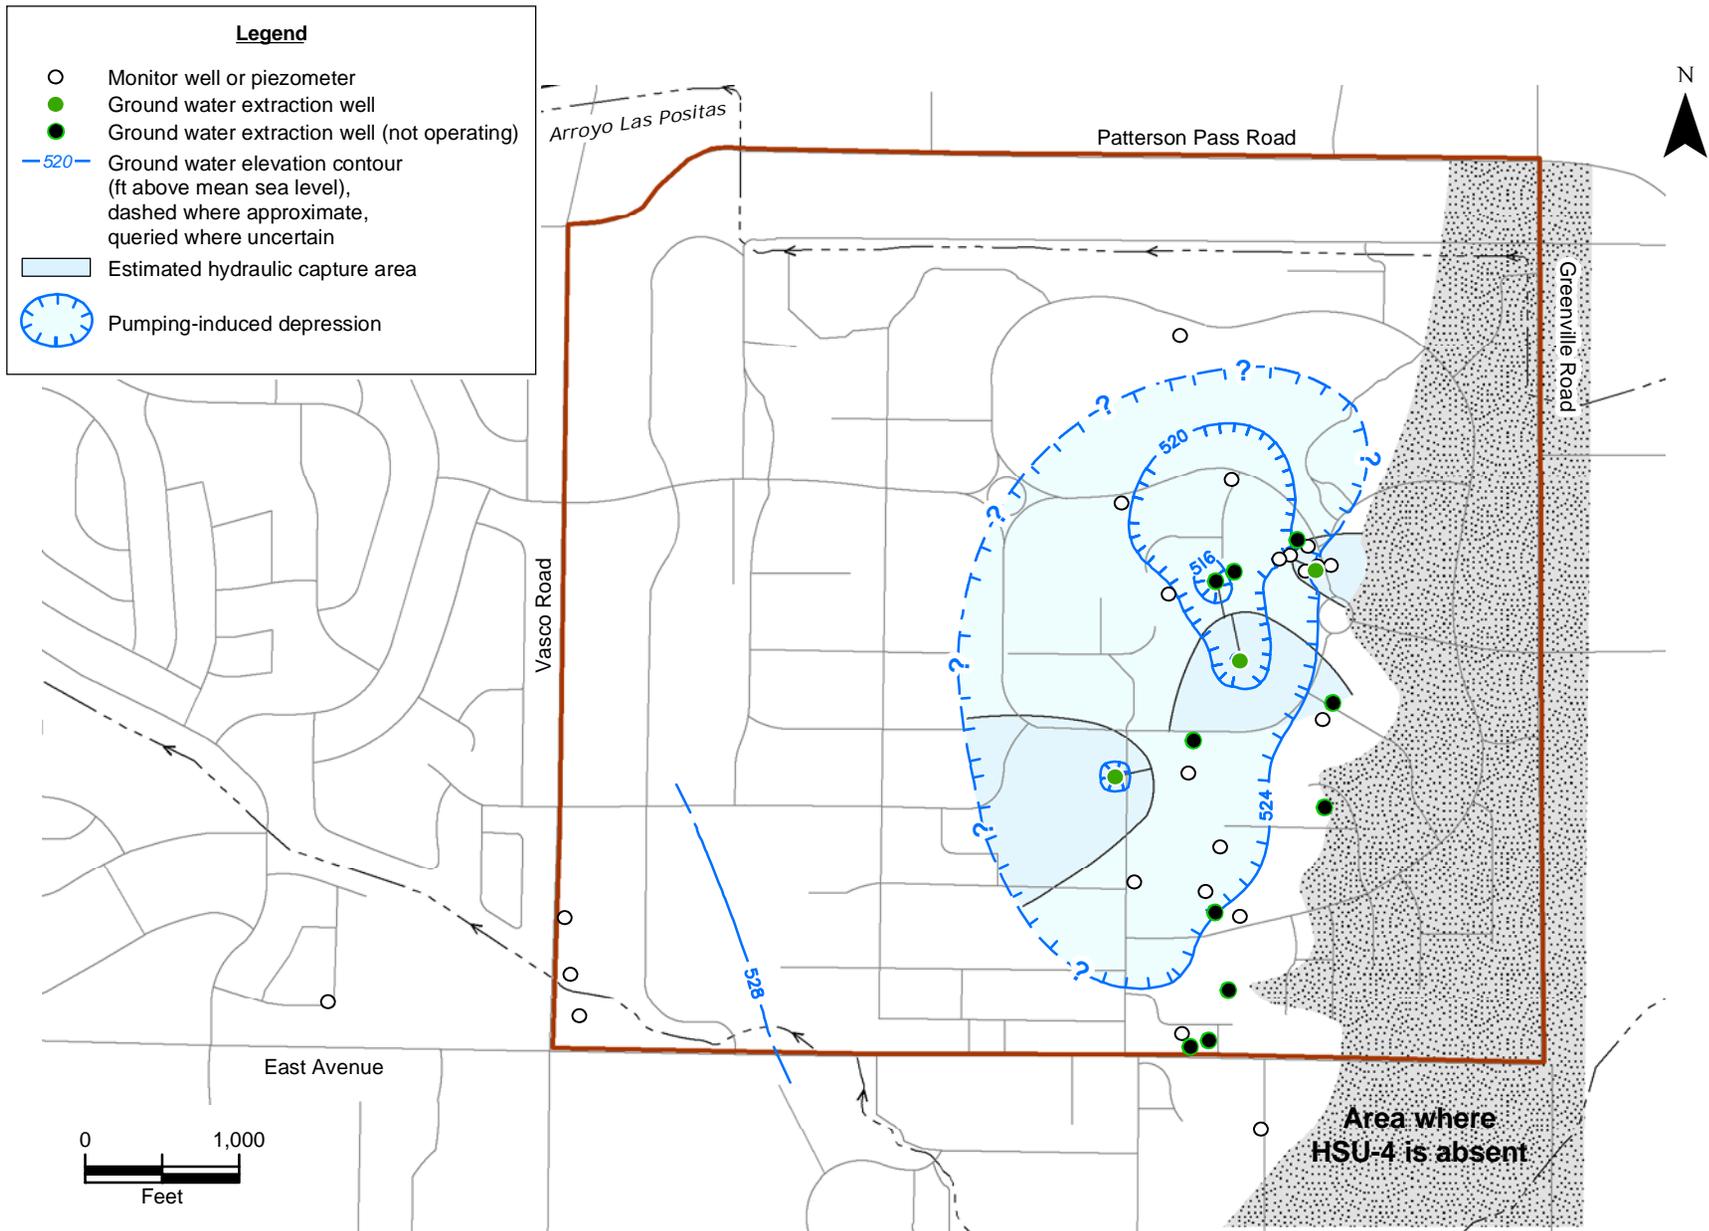

Figure 8. Ground water elevation contour map based on 35 wells completed within HSU-4 showing estimated hydraulic capture areas, LLNL and vicinity, July 2008.

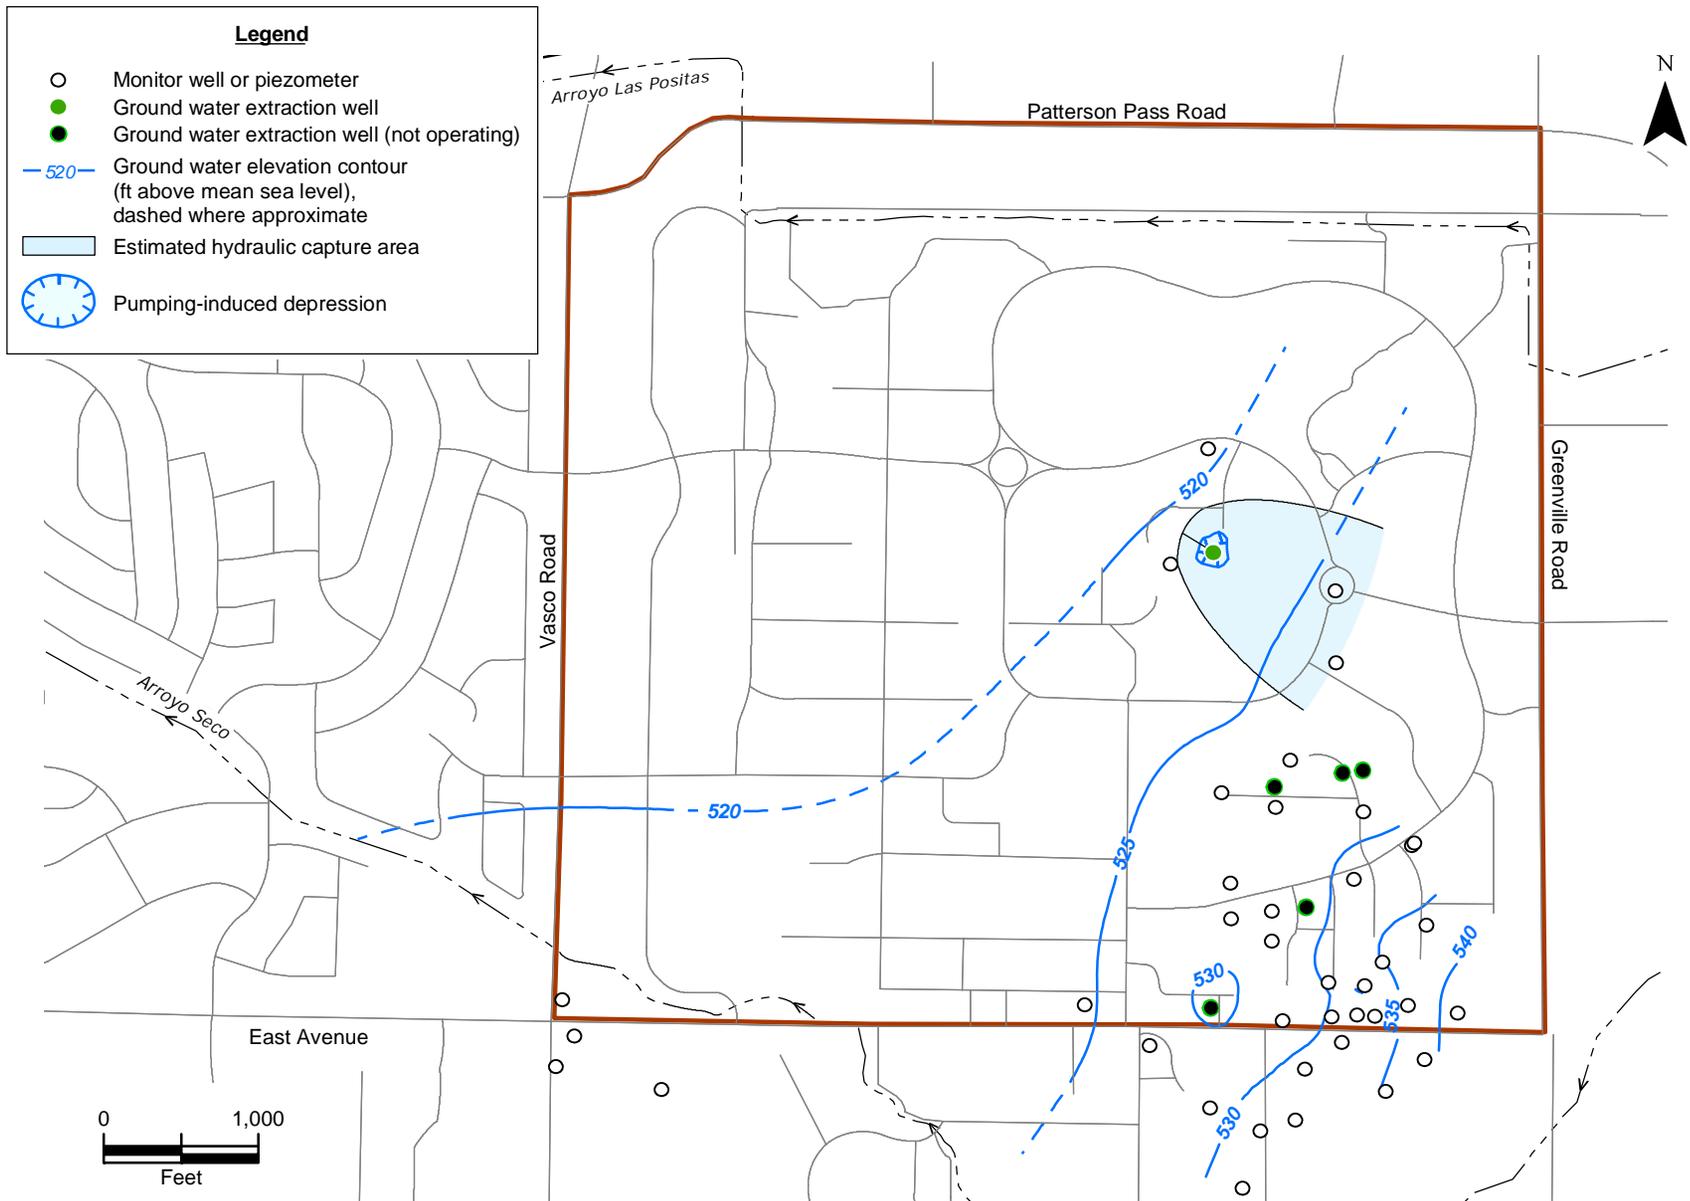

Figure 9. Ground water elevation contour map based on 45 wells completed within HSU-5 showing estimated hydraulic capture areas, LLNL and vicinity, July 2008.

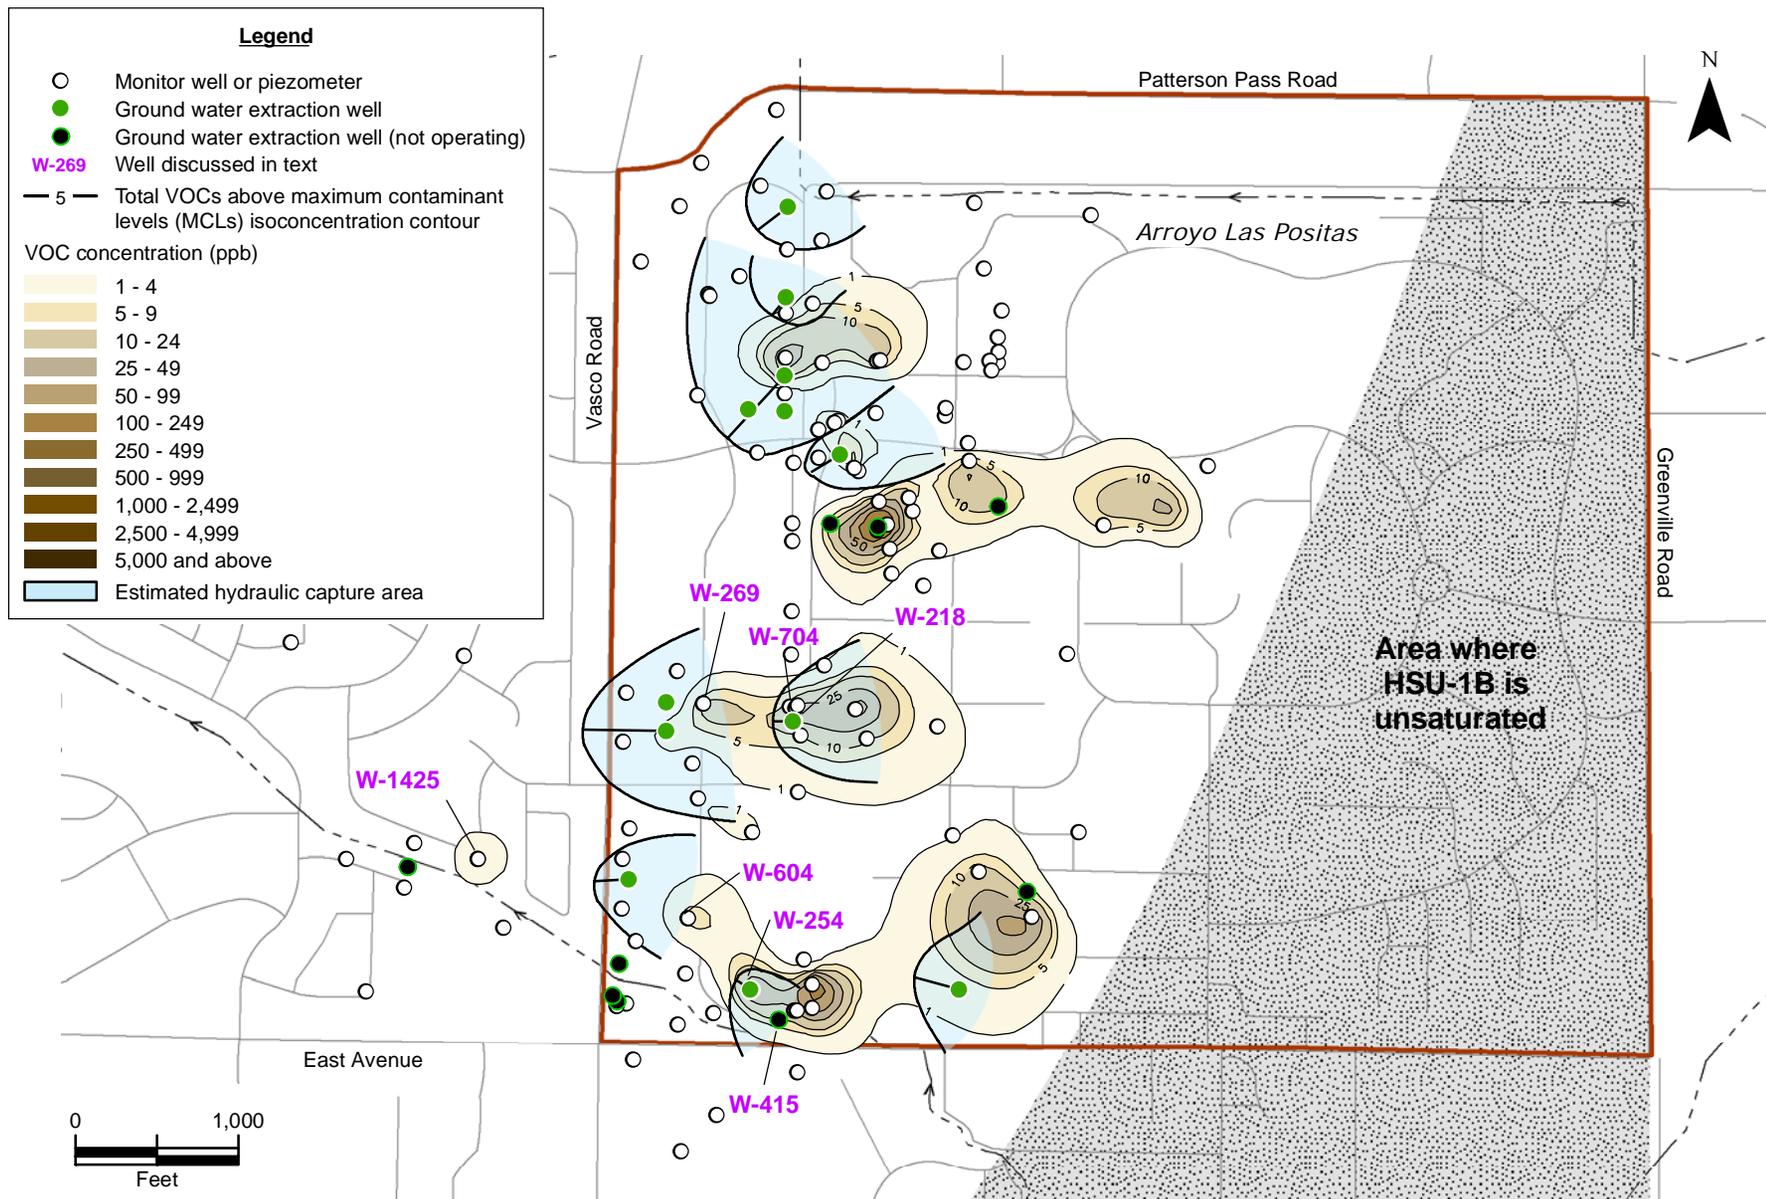

Figure 10. Isoconcentration contour map of total VOCs above MCLs from 129 wells completed within HSU-1B, third quarter 2008 (or the next most recent data), and supplemented with soil chemistry data from 38 borehole locations.

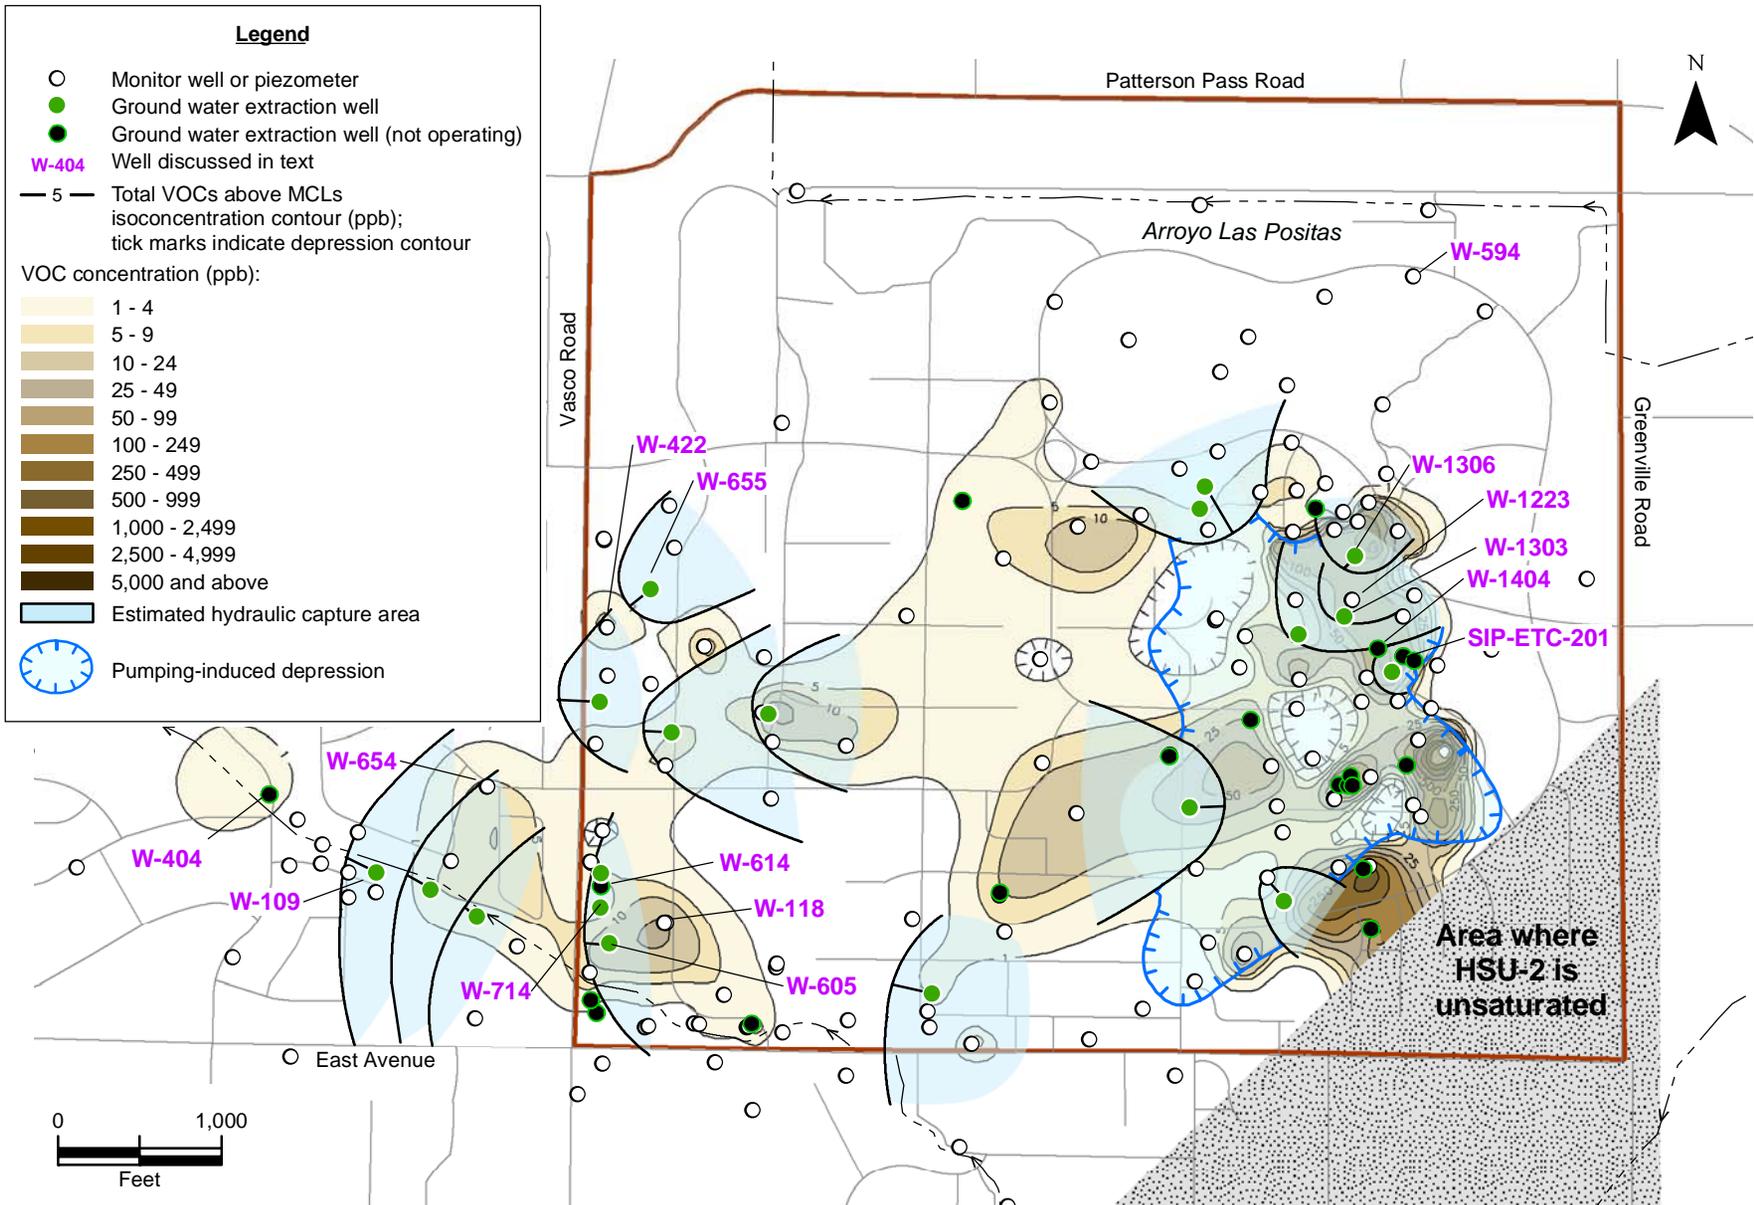

Figure 11. Isoconcentration contour map of total VOCs above MCLs from 187 wells completed within HSU-2, third quarter 2008 (or the next most recent data), and supplemented with soil chemistry data from 76 borehole locations.

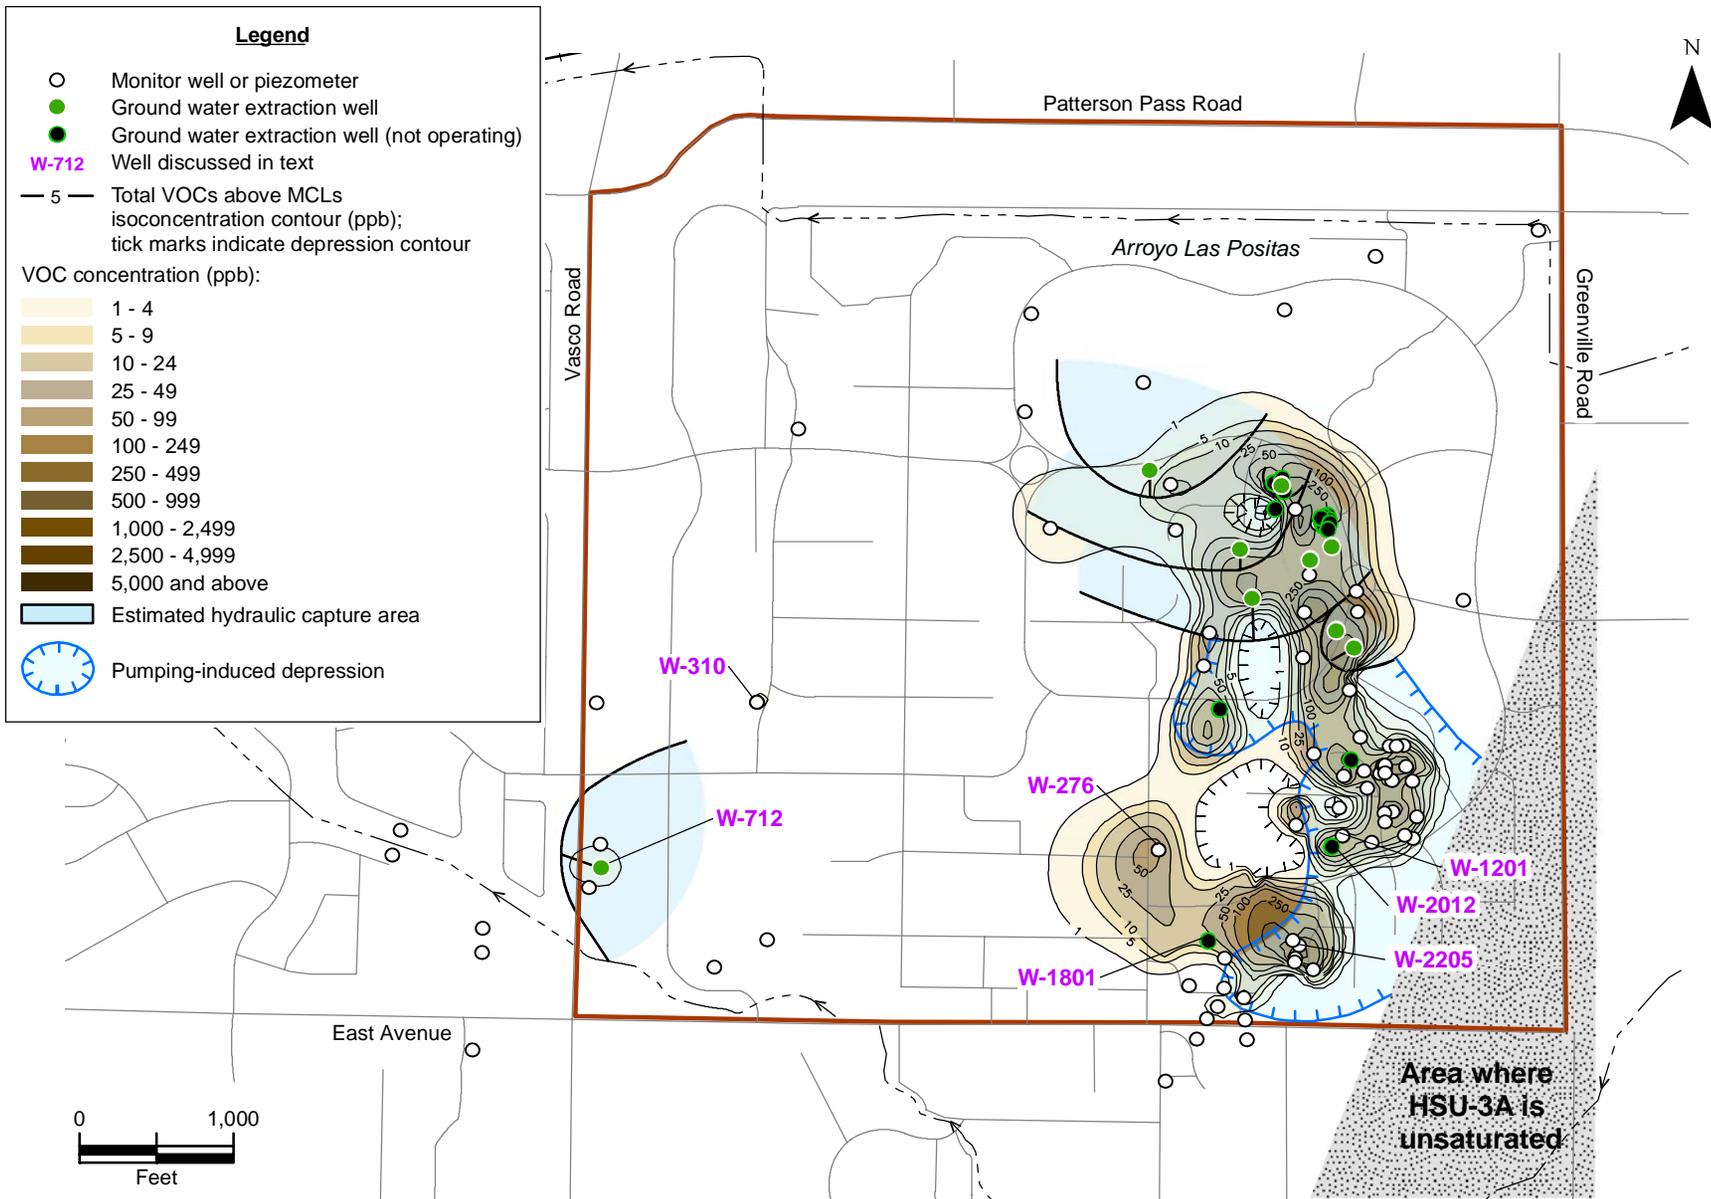

Figure 12. Isoconcentration contour map of total VOCs above MCLs from 108 wells completed within HSU-3A, third quarter 2008 (or the next most recent data), and supplemented with soil chemistry data from 142 borehole locations.

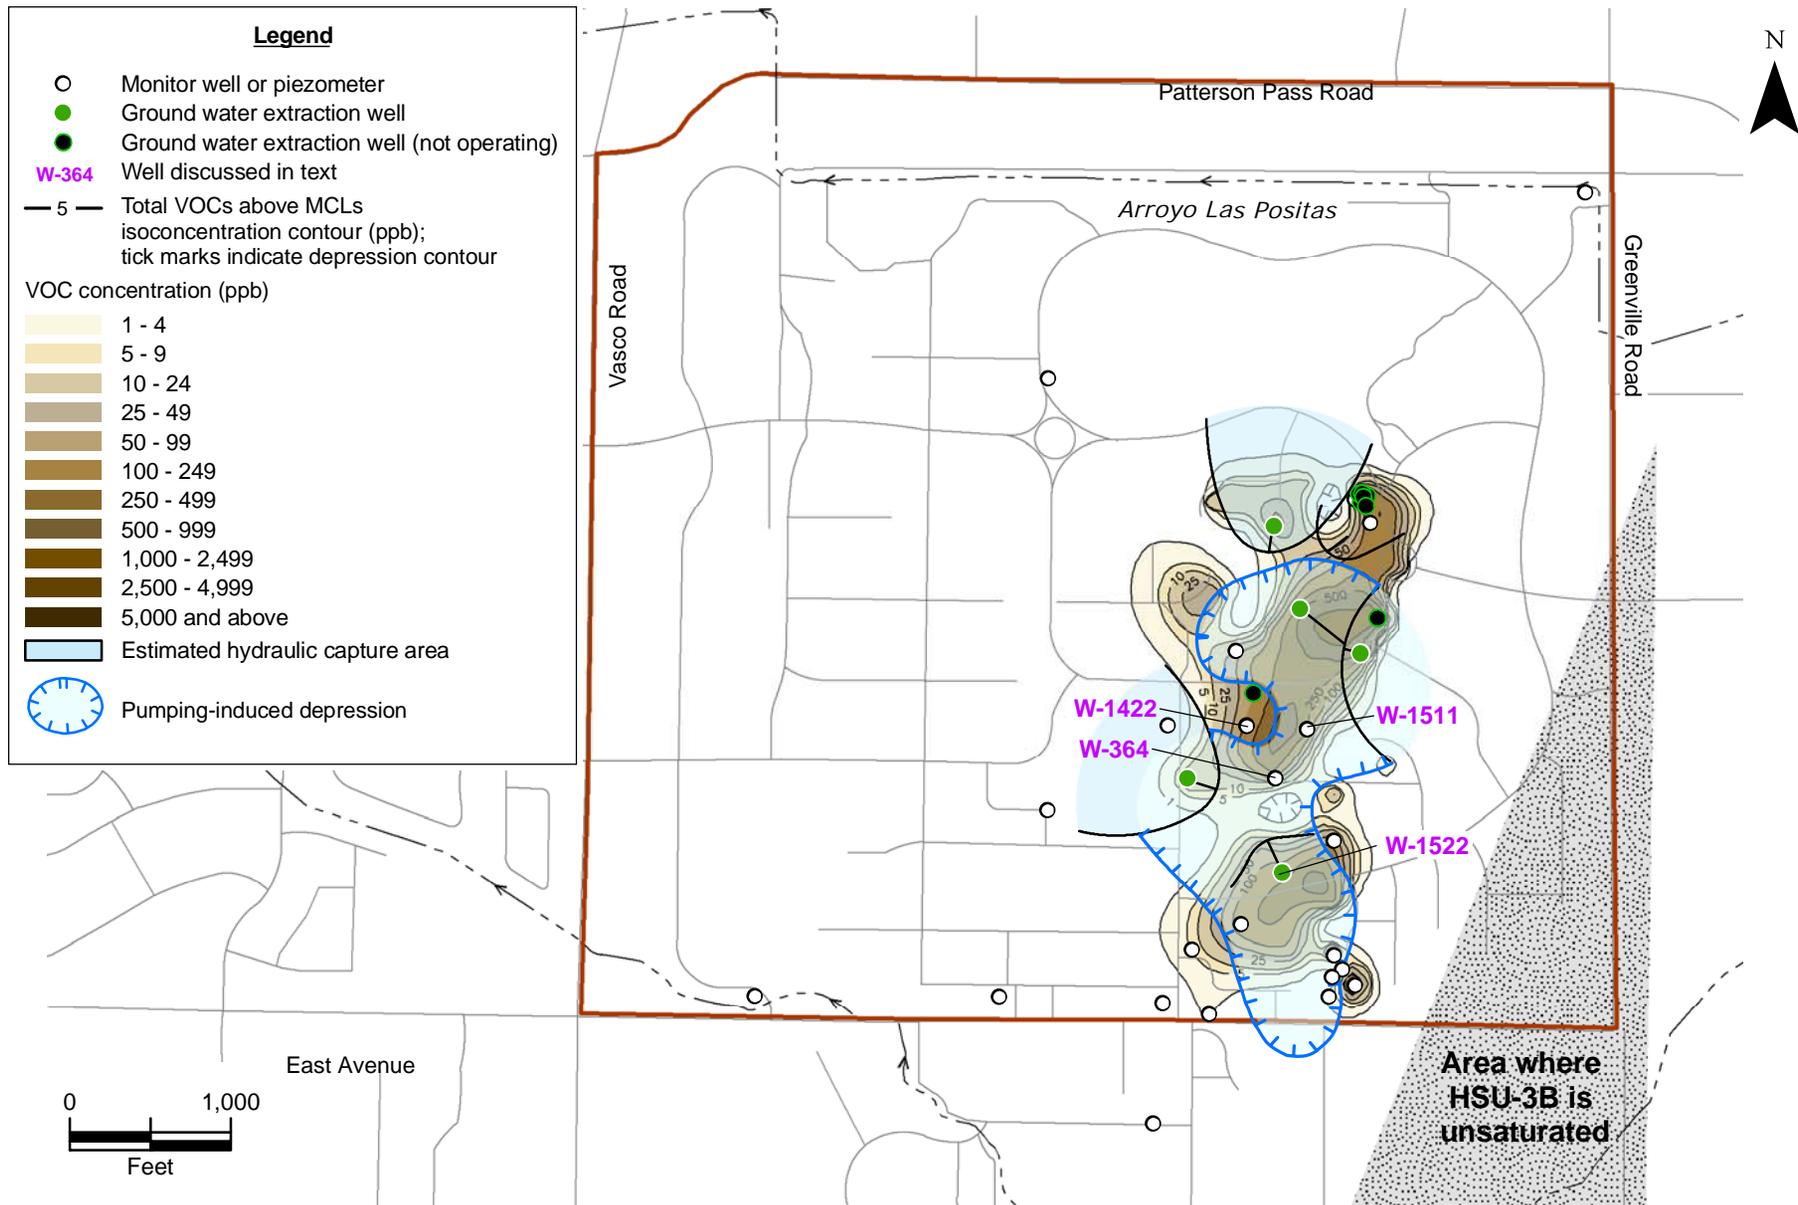

Figure 13. Isoconcentration contour map of total VOCs above MCLs from 40 wells completed within HSU-3B, third quarter 2008 (or the next most recent data), and supplemented with soil chemistry data from 108 borehole locations.

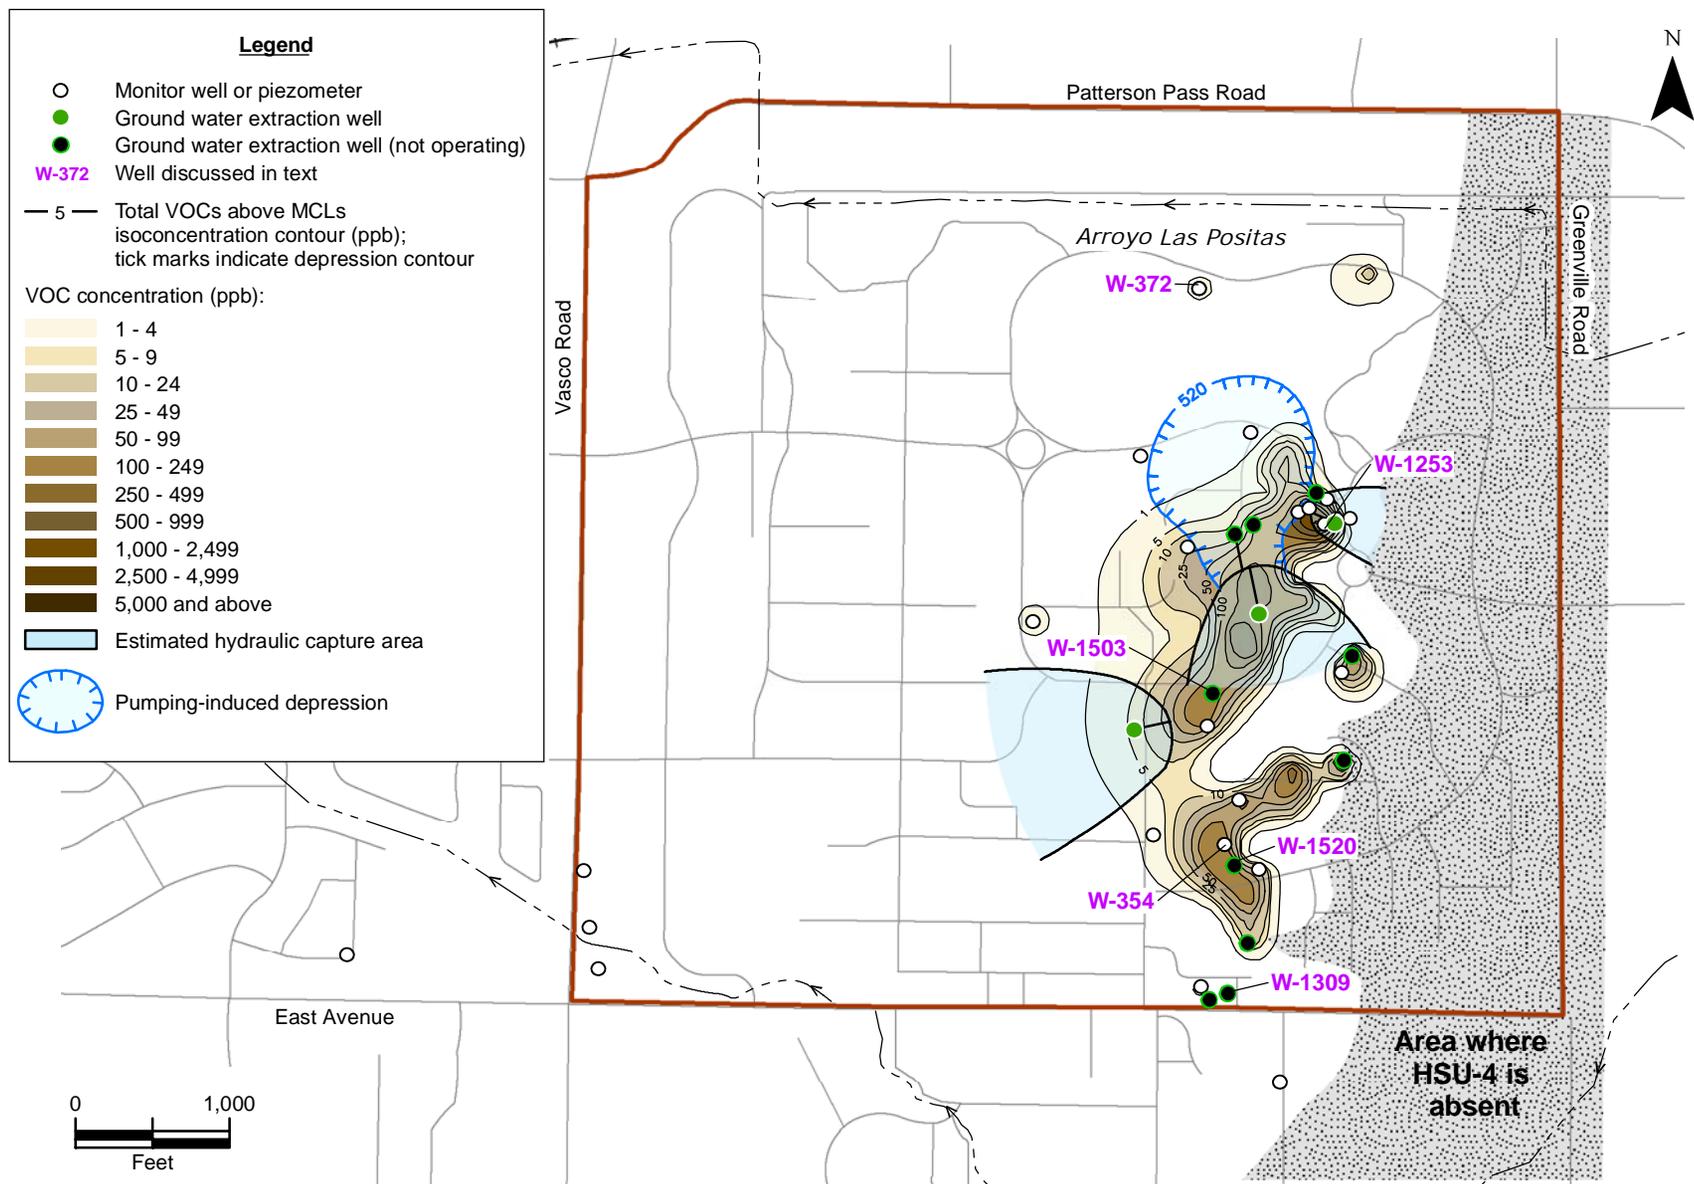

Figure 14. Isoconcentration contour map of total VOCs above MCLs from 42 wells completed within HSU-4, third quarter 2008 (or the next most recent data), and supplemented with soil chemistry data from 55 borehole locations.

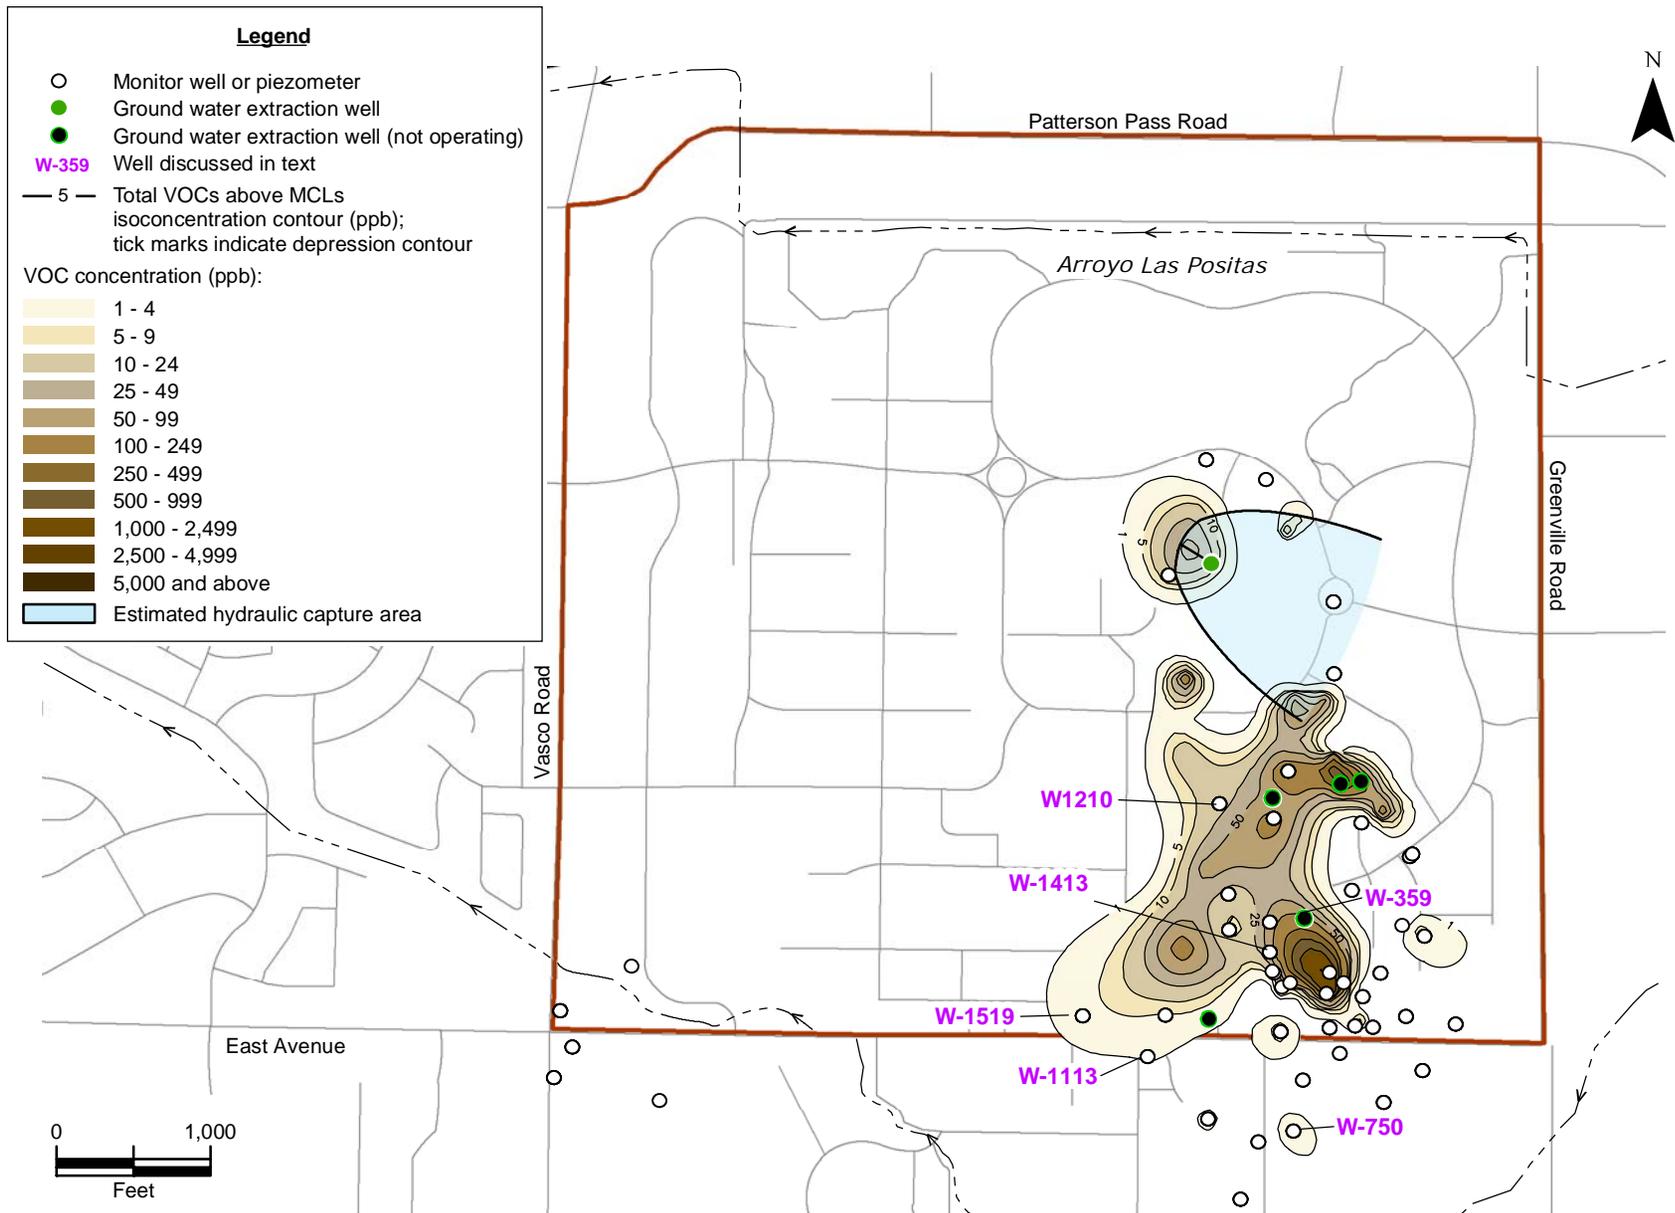

Figure 15. Isoconcentration contour map of total VOCs above MCLs from 56 wells completed within HSU-5, third quarter 2008 (or the next most recent data), and supplemented with soil chemistry data from 85 borehole locations.

Tables

Table 1. Types and numbers of Livermore Site wells.

Well type	Number of wells
Anode wells (cathodic protection)¹	9
Dual Extraction²	27
Ground Water Extraction	95
Ground Water Injection	1
Ground Water Monitor^a	395
Ground Water Guard	20
Instrumented Membrane System	5
Piezometer	111
Soil Vapor Extraction	31
Soil Vapor Injection	1
Soil Vapor Monitor	41
Total	736

Notes:

The number of Livermore Site wells is current through the end of December 2008.

Table 5 lists extraction wells and Table A-1 of Appendix A summarizes construction information for all wells.

^a Does not include 35 offsite private or agency wells that are occasionally monitored by ERD.

¹Protect metallic objects in contact with the ground from electrolytic corrosion.

²Extraction of ground water using a downhole pump with concurrent application of vacuum to the well. Ground water and soil vapor are removed in separate pipe manifolds and treated.

Table 2. Livermore Site treatment facility abbreviations.

Treatment facility	Abbreviation

Notes and footnotes appear on the following page.

Table A-1. Well construction data, LLNL Livermore Site and vicinity, Livermore, California.**Notes.**

ft = Feet.
 gpm = Gallons per minute.
 GW = Ground Water.
 HSU = Hydrostratigraphic Units.
 IMS = Instrumented Membrane Systems.
 NA = Not available.
 SV = Soil Vapor.

In wells with more than one screen, the screen positions are numbered consecutively downward within a single well. Well numbers ending in A and B, indicate two wells installations in the same borehole. The "A" refers to the shallow well and "B" refers to the deeper well.

Hydrostratigraphic Units (HSUs) are numbered consecutively downward from ground surface. An HSU is defined as sediments that are grouped together based on their hydrogeologic and contaminant transport properties. The permeable layers within an HSU are considered to be in good hydraulic communication, whereas permeable layers in different HSUs are considered to be in poor hydraulic communication. HSU contacts are interpreted and are periodically revised based on new data.

Well numbers were changed in December 1988 to be consistent with Alameda County Flood Control and Water Conservation District, Zone 7 well identification. Well number changes made on this table are:

4A6 -----> 14H2
 18D81 -----> 18D1
 14A84 -----> 14A11

Wells installed for the Dynamic Underground Stripping Demonstration Project include extraction wells (GEW series), injection wells (GIW series), gasoline spill piezometer (GSP series), and heating wells (HW series).

A FLUTE liner was installed to monitor ground water chemistry in multiple HSUs. Instrumented Membrane Systems were installed in the vadose zone to measure moisture content, pressure, temperature, and VOCs.

Piezometer SVI-518-303 was drilled out and replaced by SVW-518-1915.

Notes:

ft = Feet.
 HSU = Hydrostratigraphic unit.
 NA = Not available.

Well numbers were changed in December 1988 to be consistent with Alameda County Flood Control and Water Conservation District, Zone 7 well identification. Well number changes made on this table are:

11J81 -----> 11J4
 11R81 -----> 11R5
 11Q81 -----> 11Q6
 13D81 -----> 13D1
 14A81 -----> 14A1
 14A82 -----> 14A2
 14A83 -----> 14A4

Well 11A5 was renamed 2R9 by the Alameda County Flood Control and Water Conservation District, Zone 7 in November 1997. Well 11A5 now applies to monitor well W-409.

“Other non-LLNL” refers to agricultural, private or agency wells.

Piezometer SVI-518-303 was drilled out and replaced by well SVW-518-1915.

Temperature monitoring wells (TEP series) consist of a blank fiberglass 2-in. inside diameter (ID) casing instrumented with geophysical sensors. The blank fiberglass casing has no screened interval. Some boreholes also had one or two 1-inch piezometers installed adjacent to the blank casing. Therefore, the casing depths with accompanying screened intervals refer to the piezometers.

^a Well 11BA not recognized by Alameda County Flood Control and Water Conservation District, Zone 7.

Notes and footnotes appear on the following page.

Table B-1. Results of hydraulic tests.^a**Notes:**

- gpd = Gallons per day.
 gpm = Gallons per minute.
 NA = Not applicable.
 sq ft = Square feet.
- ^a The pumping test results were obtained by using the analytic techniques of Theis (1935), Cooper and Jacob (1946), Papadopoulos and Cooper (1967), Hantush and Jacob (1955), Hantush (1960), or Boulton (1963). The particular method used depends on the character of the data obtained. The slug test results were obtained using the method of Cooper et al. (1967) (See references below).
- ^b "Drawdown" denotes 1-hr pumping tests; "Longterm" denotes 24- to 48-hr pumping tests; "Slug" denotes monitoring and recovery after an instantaneous change in ground water elevations; "Step" denotes a step-drawdown test, flow rate given is the maximum or final step. "Injection" denotes the introduction of treated ground water under gravity into a well.
- ^c K is calculated by dividing T by the thickness of permeable sediments intercepted by the sand pack of the well. This thickness is the sum of all sediments with moderate to high estimated conductivities determined from the geologic and geophysical logs of the well.
- ^d Hydraulic test quality criteria:
 Excel: High confidence that type curve match is unique. Data are smooth and flow rate well controlled.
 Good: Some confidence that curve match is unique. Data are not too "noisy." Well bore storage effects, if present, do not significantly interfere with the curve match. Boundary effects can be separated from properties of the pumped zone.
 Fair: Low confidence that curve match is unique. Data are "noisy." Multiple leakiness and other boundary effects tend to obscure the curve match.
 Poor: Unique curve match cannot be obtained due to multiple boundaries, well bore storage, uneven flow rate, or equipment problems. Usually, the test is repeated.

Notes:

cm² = Square centimeters.

Hg = Mercury.

HSU = Hydrostratigraphic unit.

Max. conc. = Maximum concentration.

NM = Not measured.

ppm_v = Parts per million by volume.

scfm = Standard cubic feet per minute.

NC = Not computed due to insufficient data for analysis.

NA = Not applicable.

^a Sample collected in Tedlar bag for TO-14 or TO15-01 analysis.

^b Sample measured with organic vapor analyzer.

Notes:

All analyses are by EPA Method 601 for purgeable halocarbons.

E = Even years.

O = Odd years.

A = Annual.

S = Semiannual.

Q = Quarterly.

Q1 = First Quarter.

PRAD = Permits and Regulatory Affairs Division. Analyses are for the environmental surveillance monitoring programs carried out at DOE sites to complement restoration activities.

^a Wells completed with two discrete screened intervals which are hydraulically isolated from one another by a packer and are sampled individually.

Lake Hausmann
Annual Monitoring Program

Appendix E

Lake Haussmann Annual Monitoring Program Summary

This appendix summarizes the LLNL Environmental Protection Department discharge data for Lake Haussmann. Lake Haussmann is an artificial water body with an underlying liner to prevent infiltration. It was re-surveyed in 2000 and shown to have a capacity of about 37 acre-ft (12 million gallons). Lake Haussmann is located in the central portion of the Livermore Site (Fig. E-1) and receives storm water runoff and treated ground water. Discharge from Lake Haussmann flows north through a culvert into Arroyo Las Positas.

Samples are collected from water discharge from Lake Haussmann and analyzed as outlined in Jackson (2002). The discharge samples are used to determine compliance with discharge limits in the *Record of Decision* (DOE, 1992), and the subsequent *Explanation of Significant Differences for Metals Discharge Limits* (Berg et al., 1997).

Dry season (June, July, August, September) discharges are sampled during each manual release or monthly during periods of continual release. Wet season (October through May) discharge samples are collected during the first release of the wet season and one other discharge in conjunction with a storm water monitoring event. Analytical results of discharge samples collected at sampling location CDBX are compared with the LLNL Arroyo Las Positas outfall sample results collected at sampling location WPDC (Fig. E-1).

The analytical results for release samples were reported in the LLNL Livermore Site Quarterly Self-Monitoring Reports (Yow and Wong 2008a, b, c, and 2009).

E-1. Lake Haussmann Discharge Monitoring

Releases from Lake Haussmann remained continuous throughout the year, with one exception. Invasive species mitigation in Arroyo Las Positas required the temporary cessation of upstream discharges. No discharge from Lake Haussmann occurred from October 20 through November 10, 2008, to support this mitigation effort. Release samples for the 2007-2008 wet season were collected on October 8 and December 18, 2007. Release samples for the 2008-2009 wet season were collected on October 13, 2008, and January 22, 2009. An additional wet season sampling event occurred on December 1, 2008, to resample for chronic toxicity testing. Dry season samples were collected on June 24, July 23, August 19, and September 24, 2008. Data are not yet available for the January 22, 2009, sampling event from the analytical laboratories.

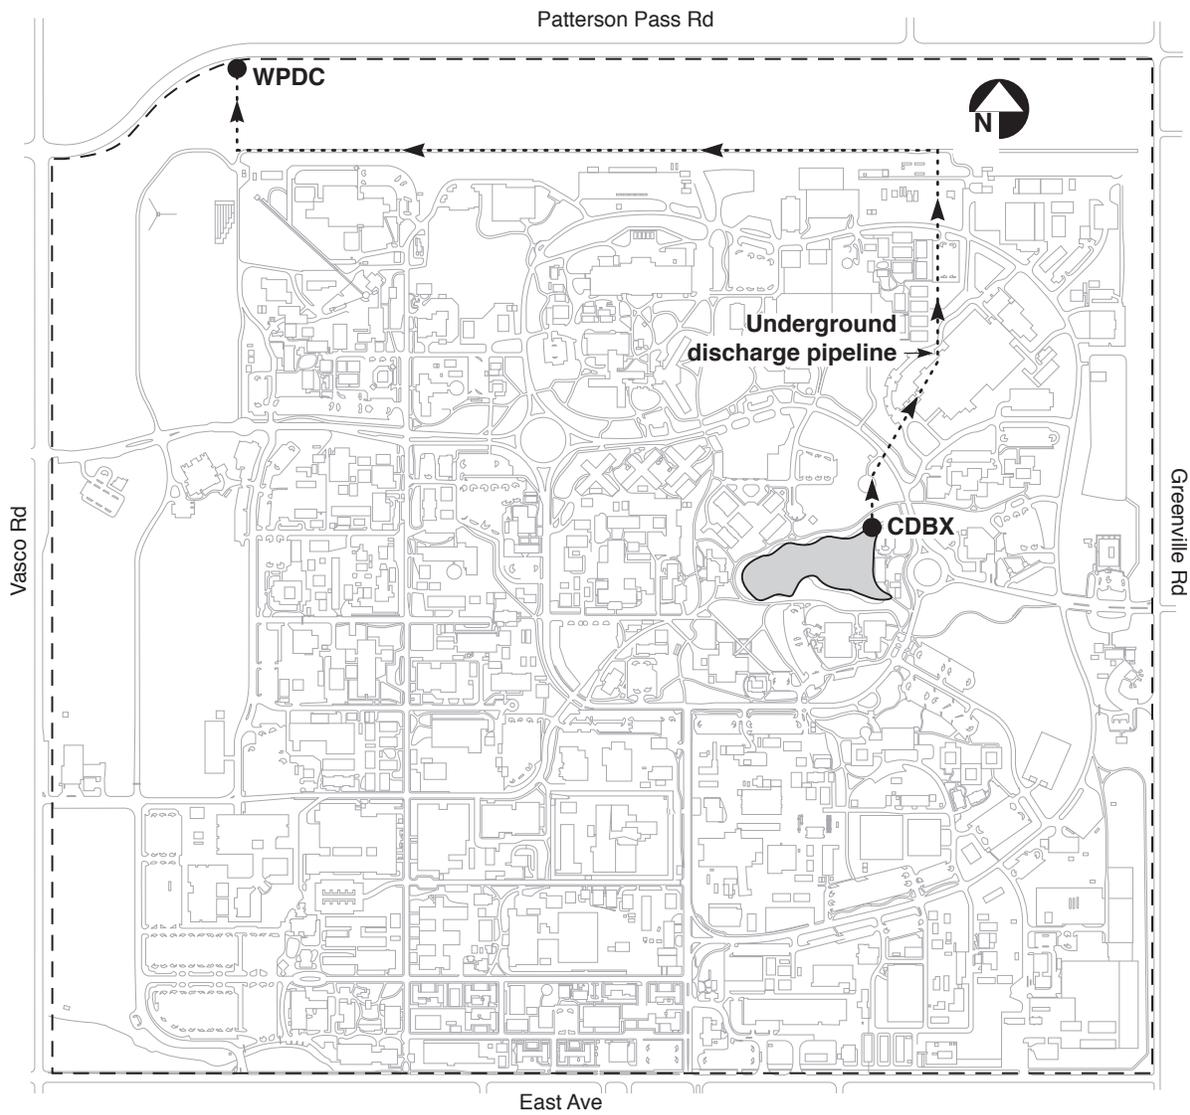

Samples from Lake Haussmann were within discharge limits for all parameters except pH. Samples collected at CDBX exceeded the pH 8.5 limit in all five reported wet and dry season monitoring events, with a maximum of 9.79. Corresponding samples collected at location WPDC exceeded the pH discharge limit in three of the five reported monitoring events. The maximum pH at WPDC was 8.83. Since 1998, the pH has averaged 8.8 at CDBX and 8.5 at WPDC and is typically higher during the summer due to increased photosynthesis. Several metals were detected above detection limits at both CDBX and WPDC; however, all of the analytical results were below discharge limits. All acute aquatic survival bioassay tests resulted in satisfactory

survival of the test species. One chronic toxicity test resulted in a significant reduction in reproduction for one of the three tested aquatic organisms, the water flea (*Ceriodaphnia dubia*) at the CDBX sampling location (October 13, 2008). The cause for this impaired reproduction in the one sample is unknown. A follow-up sample was collected at the CDBX location on December 1, 2008. This chronic toxicity test demonstrated a 100% survival and reproduction rate in the water flea.

Lake Haussmann release samples were also analyzed for VOCs, herbicides, and polychlorinated biphenyl compounds. All analytical results were below detection limits.
